Suite 115
Tampa, Florida 33618

Dear Peter,

Enclosed is a draft copy of the report "Biodegradation of the Pyroligneous Acid Fraction of Charcoal Production Wastes in Ground Water at Kingsford, Michigan". The report has not yet received U.S. Geological Survey approval and, therefore, should be considered only as a draft.

The report discusses the isotopic and chemical evidence for a single source material for the samples taken at GMSB-2A, GMSAB-2B, and GM13. Even though the samples are along different flow paths, the source location is most likely from spillage and leakage at or near the distillation areas of the plant.

The report also gives the findings of the recently completed laboratory biodegradation study of a water sample from GMSB-2B. Also included in the study are the methanogenic Total Organic Carbon (TOC) biodegradation rate constants and the methane production rate constant. Yield coefficients for the production of methane, carbon dioxide, and biomass based on TOC utilization are also included.

I hope that the report and included references contain the information that you require. Please call me if more information is required or you have any further questions.

Sincerely,

E M Godsy

Biodegradation of the Pyroligneous Acid Fraction of Charcoal Production Wastes in Ground Water at Kingsford, Michigan

by

E. Michael Godsy and Ean Warren
U.S. Geological Survey
Menlo Park, California

Background

Description of Problem

On July 12, 1995, an explosion occurred at 2104 West Breen Street in the City of Kingsford, Michigan. The explosion was apparently caused by methane gas that leaked into the basement from the surrounding subsurface. Subsequent studies by the U.S. Environmental Protection Agency, the local power company, and consulting engineers determined that the CH_4 in the residence resulted from high concentrations of this compound in the soil gas. The occurrence of CH_4 was localized around this residence and subsequently, a soil gas vapor extraction system was installed that alleviated the high CH_4 concentrations. A second occurrence of high methane concentration in soil gas was discovered approximately 300 m southeast at 2001 Emmet Street. Further laboratory and engineering studies determined that the gas was biogenic and recent in age. A third known CH_4 seep is located west of the plant site in a shallow bay section of the Menomonee River.

Large amounts of organic wastes have been dumped into natural depressions adjacent to and possibly leaked or spilled in an industrial area northeast of the explosion site. Due to the local geology, the aquifers beneath the plant site area, the depressions and the explosion site are interconnected. In addition, the overlaying clay layers that separate the aquifers are discontinuous in some places. Organic compounds including volatile fatty acids (VFAs), polynuclear aromatic hydrocarbons (PAHs), and phenolic compounds found in the wastes migrated into these lower aquifers. In some areas, VFAs are found at 6,000 to 7,000 mg/L and phenolic compounds at 50 to 60 mg/L (Westjohn and Godsy, 1997). After the natural bacteria in the aquifers depleted other electron acceptors in the ground water - O_2, NO_3^-, SO_4^{2-}, and Fe^{3+} - microorganisms produced CH_4 and CO_2 from the wastes creating plumes in the lower aquifers. In areas near the river where the hydraulic gradient is upwards, methane in the ground water is super-saturated with respect to atmospheric pressure, and where there

are openings in the confining layer(s), CH_4 escapes into the overlaying aquifer and unsaturated zone (Westjohn et al., 1996; Westjohn and Godsy, 1997). The house with explosive levels of methane had this misfortune to be situated over some of these discontinuous portions of the clay layers.

Nature of Wood Carbonization Products

From approximately 1921 until 1951, Ford Motor Company (Ford) manufactured wooden automobile parts to the northeast of the explosion site. That operation yielded approximately 3.63×10^5 kg or 363 t (metric tons) of scrap wood per day from the sawmill and body plant (Nelson, 1930). To utilize the scrap, a wood carbonization and by-products distillation plant was built which produced several commercial products:

1. *Charcoal* - approximately 300 kg/t of wood.

2. *Noncondensable Gas* - approximately 160 m^3 combustible gases/t of wood (mostly H_2, CH_4, and C_2H_6).

3. *Wood Creosote/Tar* - approximately 14 L creosote, 33 kg pitch, and 91 L of soluble tar/t of wood. These products consisted mainly of PAHs and phenolic compounds.

4. *Pyroligneous Acid* - approximately 460 L/t of wood. This fraction consists of 12.5% acetic acid, 4.5% methanol, smaller amounts of other volatile fatty acids, solvents, and phenolic compounds.

The pyroligneous acid fraction (PA) prior to 1928 was recovered by mixing with lime and recovering the acetic acid as a calcium acetate precipitate. At this time, the growing demand for ethyl acetate resulted in the direct distillation of this fraction into the various products and the production of ethyl acetate from acetic acid in the presence of ethyl alcohol and sulfuric acid (Nelson, 1930).

The various alcohols and solvents produced by the distillation plant were of standard purity and were chiefly sold outside of the company, with the exception of ethyl acetate, the production of which was largely utilized in making the lacquer finish and artificial leather for the Ford car. Non-commercial products also generated were combustible gases, wood pitch, wood creosote, and wood tar. Most of these non-commercial products were used as fuel for the kilns during charcoal production. The remaining non-commercial products or wastes consisting of "off specification" chemicals, and residual products were periodically dumped

into two natural depressions; a primary site consisting of two interconnected natural surface depressions which received the "off specification" creosote and general plant wastes and a secondary site where wastes were comprised primarily of wood charcoal and tar (EWA Engineers, 1986 and 1987). From 1951 until 1961, Kingsford Chemical Co. obtained the wood carbonization plant and continued the production of charcoal and the off-loading of the wastes to both the primary and secondary sites.

Laboratory Investigations

Compound Specific Isotopic Analysis for Source Identification

Compound Specific Isotope Analysis was used to determine the $\delta^{13}C$ ratios of individual organic compounds within the plume. The purpose of carbon isotope analyses is first to derive a signature of the most prominent compounds in order to identify the potential source area or areas. Secondly, the isotopes may be useful to trace the degradation process occurring along a flow path. Four samples from three sites were studied: (1) two depths west of the plant site at the I° disposal site, GMSB-2A (74.7 m) and GMSB-2B (80.1 m); (2) south west of the plant site but along a different flow path at GM13 (grab sample at 44.2 m); and (3) GM2B (82.6 m), a well along the flow path of GM13 where microbial degradation has significantly lowered contaminant concentrations .

Individual organic components were identified by Gas Chromatography/Mass Spectrometry (GC/MS) on a Finnigan-GCQ. Isotopic analyses were performed by Gas Chromatography/Isotope Ratio Mass Spectrometry (GC/IRMS) using an HP 5890 gas chromatograph attached to a VG Optima mass spectrometer. VFAs and phenolic compounds were extracted from ground water samples using 1:1 and 10:1 acid extracts into diethylether for sample identification and isotope analysis, respectively. The GC columns used for both instruments were 0.25 mm I.D., 30 m DB-WAXETR (J&W Scientific, Folsom, Calif.) with a film thickness of 0.25 μm. For isotopic ratio analyses, individual organic compounds are separated by the GC and passed through a CuO furnace where they are combusted to CO_2. Water is cryogenically trapped while the CO_2 is admitted to the mass spectrometer. The CO_2 is ionized, accelerated down a flight tube and swept past a magnetic field that separates the ions by mass into individual beams. The beams strike Faraday cups producing currents proportional to their abundance. Isotope ratios and delta values are derived from these measurements.

Isotope analysis of the dissolved VFAs and phenolic compounds at the sites with high contaminant concentrations GMSB-2A, GMSB-2B and GM13 gave $\delta^{13}C$ values of approximately -30 ‰, -20 ‰, and -27 ‰ for acetate, propionate and butyrate, respectively. The phenolic compounds in these samples taken near the source, although at much lower concentrations than VFAs, appeared to have $\delta^{13}C$ values of about -27 ‰. Although GMSB-2A and GMSB-2B do not lie on the same flow path as GM13, the isotopic data supports the chemical evidence (Figures 1, 2, and 3 respectively) that the source of the contamination is similar for both locations. Very little microbial degradation appears to have occurred at these sites, which can be attributed to the microbial toxicity of the undiluted PA. Analysis of the dissolved organics from the down gradient site GM2B (Figure 4) gave a carbon–isotope ratio of -14.2 ‰ for acetate and -14.8 ‰ for 3-ethylphenol. Microbial degradation is occurring upgradient from and at GM2B, as evidenced in both the change in concentrations and the large shift in $\delta^{13}C$ of these compounds. Values for $\delta^{13}C$ have become much heavier for both compounds It is assumed that the original VFAs have been completely consumed and that the acetate at this site is an intermediate compound during microbial degradation of higher molecular weight phenolic compounds. All VFAs and phenolic compounds in well water samples tested were at or below detectable limits after traveling approximately 1000 m down gradient from the plant area.

Toxicity and Microbial Enumeration of Water and Sediment Sample

Water and sediment samples from the grab sample at GMSB-2A were tested for the presence of microorganisms that might be present in an anoxic-methanogenic environment. Microorganisms capable of (1) aerobic heterotrophic growth, (2) growth under denitrifying conditions, (3) growth under sulfate-reducing conditions, (4) growth under anaerobic heterotrophic fermentative conditions, (5) growth under anaerobic iron reducing conditions, and (6) growth under methanogenic conditions using H_2 and CO_2, acetate, and a mixture of both substrates were tested for growth (Godsy *et al.*, 1992) and the results are given in Table 1.

The water sample from GMSB-2A tested did not contain any culturable microorganisms (<1 cell/0.1 mL GMSB-2A); however, the corresponding sediment sample contained 10^5 or greater total microorganisms/g dry weight sediment. The microbial population present on the sediment appears to be anaerobic in nature. The population capable of aerobic growth consists of facultative anaerobes also capable of denitrification and anaerobic fermentation. The high numbers of iron reducing bacteria and lack of methanogenic microorganisms

suggests that the sediment sample came from an area were iron reduction predominates, not methanogenesis. This finding is also supported by the low dissolved CH_4 (16 mg/L) at GMSB-2 at 74.7 m below land surface (BLS) while the dissolved CH_4 value at 80.1 m was 155 mg/L (Arcadis Geraghty & Miller, Inc., 1998). Microcosms containing only the sediment and ground water from 74.7 m BLS incubated at 20°C did not produced detectable amounts CH_4, but produced high concentrations of CO_2 and dissolved iron (Fe^{2+}). Analyses of the chemical constituents present before and during growth were not performed on this series of experiments. The lack of culturable microorganisms in this water sample strongly implies that the water is somewhat hostile to microbial growth unless there is dilution with the native ground water. The viable, but not methanogenic, anaerobic microbial population on the sediment suggests that protection is provided within the sediments.

This finding provides a possible explanation as to why such a readily biodegradable material has persisted for many years in the subsurface. The PA is moving vertically downward due to the hydraulic gradient and laterally with the ground water flow. This can be seen at GM13, just south of the plant area, where the PA fraction was encountered in a grab sample taken at 44.2 m below land surface, but not in samples from the bedrock well location (99.1 m). When the PA mixes with the ground water during down gradient travel in the higher conductivity lenses, the inhibition is relieved by dilution with ground water, and degradation of the waste begins. The other sites where PA fractions were encountered (GMSB-2A, GMSB-2B, and GM2B) were located farther southwest and south of the plant site and deeper towards bedrock, respectively.

Biodegradation of Pyroligneous Acid Fraction

Microbial Growth and Substrate Utilization

The growth of a microbial population is a complex phenomenon composed of a number of simultaneously occurring events. Relative magnitudes of the respective rates determine the net effect upon the population. The primary events are the utilization of substrate and the concurrent growth of the organisms. These two events are closely related because it is only through the utilization of substrate that energy and carbon are made available for cell growth.

Bacteria divide by binary fission and consequently the number of viable cells will increase in an exponential fashion. The reaction rate for bacterial growth can be expressed as a first-order equation

$$\frac{dX_a}{dt} = \mu X_a$$

where X_a is the concentration of active bacteria (mg/L), and μ is the specific growth rate (day^{-1}). The growth rate constant is referred to as a specific growth rate because it defines the rate of cell growth in terms of the concentration of cells present.

The growth yield, Y (mg/mg), is defined as the ratio of the rate of cell growth to the rate of substrate, S (mg/L), removal. This can be expressed mathematically as

$$-\frac{dS}{dt} = \frac{\mu}{Y} X_a$$

Consequently it can be seen that the rate of substrate removal is first-order with respect to the concentration of viable cells. The effect of the concentration of growth limiting nutrient upon the specific growth rate (μ) is a function of the initial substrate concentration and μ increases as the substrate concentration is increased until it approaches some maximum value (μ_{max}).

The question of the best mathematical formula to express the relationship of the growth rate and substrate concentration has been a subject of much debate. No one yet knows enough about the mechanisms of microbial growth to propose a mechanistic equation which will characterize growth exactly. Instead, experimenters have observed the effects of various factors upon growth and have attempted to fit empirical mathematical equations to their observations. The equation with historical precedence and greatest acceptance is the one proposed by Monod (1949)

$$\mu = \frac{\mu_{max} S}{K_s + S}$$

where K_s (mg/L) is the half-saturation constant. K_s determines how rapidly μ approaches μ_{max} and is defined as the substrate concentration at which μ is equal to half of μ_{max}.

The above relationships can be combined into an expression that relates substrate utilization to bacterial growth.

$$-\frac{dS}{dt} = \frac{\mu_{max} X_a S}{Y(K_s + S)}$$

These expressions can be combined into one equation that relates bacterial growth and decay to substrate utilization.

$$\frac{dX_a}{dt} = \frac{\mu_{max} X_a S}{K_s + S}$$

The above equations are general expressions of a system in which only population densities and substrate concentration determine the kinetics of degradation. When the inoculum density is extreme compared to the substrate concentration or, when substrate concentration is very low or very high with respect to K_s, the Monod equation may be simplified to 5 special forms or Monod family of equations (Table 2). When the initial bacterial density is much greater than the number of new bacteria which would be produced from the substrate at time zero, i.e., $X_o >> S_o$, the growth of population during the course of the experiment is insignificant. Similarly, when the initial substrate concentration is much greater than K_s, i.e., $S_o >> K_s$, most of the substrate will disappear while the enzyme uptake systems of the cells are saturated, and $K_s + S$ in the above equation can be approximated by only S. Alternatively, when the substrate is initially present at much less than saturating levels ($S_o << K_s$), the value of $K_s + S$ can be approximated by only K_s. These simplifications allow the modeling of the variety of shapes of substrate disappearance or product appearance curves with only substrate concentration and bacterial density and the parameters of Monod kinetics.

Laboratory Microcosms

Two identical microcosms were prepared using 4 L solvent bottles fitted with Mininert® valves to facilitate removal of water samples from one digestor and gas samples from the second digestor. Both digestors were prepared with 3.1 L of water from GMSB-2B taken at 80.1 m below land surface and 0.75 L of anaerobic domestic sewage sludge. The sludge was used as an anaerobic inoculum because of the lack of methanogenic microorganism in the water samples from GMSB-2A and presumable GMSB-2B. Before use, the sludge was aged until CH_4 production ceased and all particulate matter had precipitated. Both digestors were maintained in an O_2-free anaerobic glove box at 20±1°C.

Analytical Methods

Gas volumes were measured using a water wetted 10 mL syringe. Head space and dissolved gas composition was determined by head-space analysis using a GC equipped with a thermal conductivity detector. TOC was determined by wet-chemical oxidation method. Organic compounds were identification using GC/MS as described. Tentatively identified compounds were confirmed with certified standards. Phenolic compounds were quantified using a HPLC system consisting of a Waters 490 Detector set at 280 nm and dual ISCO 2350

pumps. The samples were run through a reverse-phase C^{18} column. The stationary phase was ammonium acetate buffer (pH 7.0) and the mobile phase was acetonitrile.

Low-molecular weight fatty acids (formate, acetate, propionate, and butyrate) were determined using a Dionex Ion Chromatography System equipped with an autosampler and a Dionex AS15 column and guard column. The AS15 column temperature was maintained at 30°C.

Substrate Utilization

After the microcosms were inoculated, a leak developed in the gas sampling valve that was not detected for approximately 60 days. The lack of gas production was mistakenly assumed to be a sign of a lack of biodegradation. When the leak was discovered, the microcosms were rezeroed, sampled, and the time set to day zero. GC/MS chromatograms show the differences in fatty acid concentrations at both times (Figure 5). The leak resulted in an unknown amount of CH_4 and CO_2 being lost during the initial biodegradation of acetate and butyrate; however, the mass balance and the kinetics of substrate disappearance and product appearance from that time forward would not be affected. As a further assurance, the rate of TOC disappearance (k_{20}) was used to back-calculate the starting TOC of the microcosm, the values agreed within 5% of the TOC of the water sample collected from GMSB-2B plus the aged anaerobic sewage sludge.

The biodegradation of the VFAs and phenolic compounds are shown in Figures 6, 7, and 8. The gas chromatogram shown in Figure 6A is that of the water sample taken from GMSB-2B for comparison before dilution with the inoculum and Figure 6B is a chromatogram of the rezeroed inoculated microcosm. The loss of the VFAs is readily apparent; however, no loss of phenolic compounds was observed. Figure 7A is a chromatogram at Day 0 and Figure 7B is a chromatogram after 93 days of biodegradation at which time the VFAs are essentially gone and the microbial population has switched to biodegradation of the phenolic compounds. Figure 8A is a gas chromatogram of the microcosm after 267 days and Figure 8B is a gas chromatogram of the microcosm after 471 days, after greater than 99% of the degradable compounds have been utilized. The shift in substrate utilization can easily be seen in Figure 9A where the rate of total gas production abruptly increases at approximately day 100. This is further verified in Figure 9B which shows the VFAs change in concentration with time and Table 3 which give the concentrations of several selected phenolic compounds during this time period. Phenol is not biodegraded until the VFAs are gone at about 63 to 106 days. Once phenol is degraded, 3- and 4-methylphenol are biodegraded after 131 days. 2-

Methylphenol does not biodegrade during this time, and is the last phenol to biodegrade around 276 days. This similar to the sequential methanogenic biodegradation of phenolic compounds observed at a former creosote plant (Godsy *et al.*, 1992).

The identified and confirmed compounds of interest in GMSB-2B are shown in Figures 10 for VFAs and 11 for phenolic compounds. Unconfirmed compounds in Figure 9 are mainly alcohols, furans, and cyclic hydrocarbons, while those in Figure 10 are mostly aromatic compounds. The majority of these compounds contained one or more side chains and are consistent with compounds attributed to the PA fraction (Hawley, 1923; Klar, 1925).

Figures 12and 13 identify those VFAs and phenolic compounds, respectfully, that were not degraded in the microcosm after 267 days. Acetate was the only VFAS present in the microcosm and is the major and last intermediate compound during the biodegradation of more complex organic compounds (*e.g.*, phenols). The concentration of acetate will decrease to a level at which the microorganisms will no longer be able to degrade the compound (~ 0.1 mg/L). At day 471, acetate could not be detected in the microcosm and of the confirmed phenolic compounds, only 2,6- and 2,4-dimethylphenol remained. This observation is consistent with published results that find that 2-methylphenol is the most difficult and slowest of the methylphenols to biodegrade under methanogenic conditions (Godsy *et al.*, 1992). Similarly, phenols with only one attached alkyl chain (*e.g.*, methylphenols and ethylphenols) are biodegradable under these conditions, while phenols with two or more alkyl chains (*e.g.*, dimethylphenols) have not been shown to be biodegradable under methanogenic conditions.

Mass Balance and Kinetic Parameters

A mass balance of carbon transformation with time was performed and is shown in Figure 14. TOC analyses of the digestor fluid indicated a loss of 53.1 mmol/L of carbon had occurred up to day 271. The TOC loss was accompanied by the production of 23.0 mmol/L of carbon as CH_4, 32.3 mmol/L of carbon as CO_2, and (not shown in Figure 14) 0.28 mmol/L of carbon as biomass. The biodegradation resulted in 105% of the carbon being accounted in the products, which may be a result of very slow biodegradation of the compounds in the inoculum; however, whatever the cause, the value is well within the experimental error observed in sampling and analysis.

Shown in Figure 15A is the disappearance of TOC (mg/L) with time in the 4L digestor. The remaining 275 mg/L TOC after day 271 is due to the recalcitrant material in the aged

anaerobic sewage digestor sludge used as the methanogenic inoculum. Shown in Figure 15B is the production of CH_4 (mg/L) with time. Using non-linear regression analysis to determine the Monod kinetic parameters, a K_s value of approximately 7000±3000 mg/L TOC was obtained. The conditions for a First-Order approximation require that very little growth ($X_{ao} >> S_o$) or a very low Y (mg cells/mg TOC) occurs and that the substrate concentration be much less than the value of K_s ($S_o << K_s$). Both conditions are satisfied and a First-Order model may be used to describe the TOC degradation and CH_4 production. The integrated form of the TOC biodegradation and CH_4 production respectively to determine the concentrations at any time t are as follows:

$$S = S_o \exp^{-kt}$$

$$P = P_o(1-\exp^{-kt})$$

where:

k is the First-Order rate constant,
S is the substrate at time t,
S_o is the starting substrate concentration,
P is the product at time t,
and P_o is the final concentration of product.

Reaction rates are strongly affected by temperature changes, but reaction stoichiometry is generally unaffected. For the First-Order model, temperature effects are accounted for in the rate constant k, using the following modified form of the van't Hoff-Arrhenius relationship:

$$k_T = A\exp^{-E/RT}$$

where:

k_T is the First-Order rate constant at T °K, day^{-1},
A is the van't Hoff-Arrhenius coefficient, day^{-1},
E is the activation energy, J/mol,
R is the universal gas constant, 8.314 J/mol•°K,
and T is the temperature, °K.

Because it is convenient to use degrees centigrade and because E for microbial systems is relatively constant (33,500 to 50,250 J/mol) the equation can be modified to account for temperature differences and rewritten as follows:

$$\frac{k_{T1}}{k_{T2}} = \exp\left(\frac{E}{RT_2} - \frac{E}{RT_1}\right)$$

$$k_{T1} = k_{T2}\exp\left[\left(\frac{E}{RT_1T_2}\right)(T_1 - T_2)\right]$$

and simplified to

$$k_{t1} = k_{t2}\theta^{(t1-t2)}$$

where:

θ is the temperature coefficient and is considered approximately constant and equal to $\exp(E/RT_1T_2)$ with a value of 1.135 for $4 < t < 20$°C and 1.056 for $t > 20$°C.

Figures 15A and B, showing the rate of TOC biodegradation and rate of CH_4 production, also give the modeled First-Order rate parameters based on the values listed in Table 4 for 20°C. The rate values adjusted for the ground-water temperature of 10°C using the van't Hoff-Arrhenius relationship are also given in Table 4.

Given in Table 5 are the calculated yield coefficients for the production of CH_4/TOC consumed and CO_2 produced/TOC consumed. It can be seen that on a per mol basis, slightly more than 40% of the carbon appears as CH_4, with slightly more than 60% appearing as CO_2. Also included in the table are the yield coefficients for CH_4 and biomass on weight (mg/mg TOC) basis.

Discussion of the Contamination Nature and Methane Source

Wastes characteristic of the wood carbonization operations are prevalent throughout the area bordering former plant site. Analyses of shallow ground-water samples, especially in a westerly direction towards the I° and II° disposal pits, contained elevated concentrations of volatile and semi-volatile compounds (Arcadis Geraghty & Miller Inc., 1998) reminiscent of the water soluble fraction of wood creosote (Hawley 1923; Klar 1925). Although these compounds pose a water quality threat, these contaminants are not present in high enough concentrations to account for the extremely high dissolved CH_4 and CO_2 concentrations observed throughout the area (155 mg/L CH_4 at GMSB-2B at 80.1 m). Water samples from wells up gradient from the former plant area did not contain significant levels of CH_4 and CO_2 or of the volatile and semi-volatile compounds.

A preponderance of evidence suggests that leakage and/or spillage of PA fraction from the distillation and transport processes at the plant site are the major source of CH_4 and CO_2 in the ground-water system. The plant area is directly up gradient from GMSB-2A, GMSB-2B, and GM13 are green-yellow in color, have a very strong odor of burnt wood, contain high concentrations of mononuclear aromatic and phenolic compounds (Arcadis Geraghty & Miller Inc., 1998), and extremely high concentrations of VFAs. All of these ground-water samples also have a lower pH and very high TOC values. Ground water samples from GM12 and other wells, directly up gradient from plant site, do not contain significant levels of CH_4 and CO_2 and do not contain volatile or semi-volatile contaminants or VFAs. Samples from GM2B, approximately 425 m south of GM13, contained approximately one-fourth the concentrations of VFAs and apparently has been biodegraded and diluted with ground water during down gradient travel. In addition, the VFAs in ground-water samples from these wells have an identical isotopic signature, adding credence to the plant area as the source.

The majority of the dissolved compounds in ground water samples from the PA fraction (GMSB-2B) have been shown to be anaerobically biodegradable to CH_4 and CO_2 in laboratory microcosms. The biodegradable compounds, and the rates and amounts of CH_4 and CO_2 produced in the microcosms are consistent with observations form field samples.

It is apparent that methanogenesis of the PA begins after dilution with ground water after approximately400 m downgradient travel in the direction of the ground-water flow. The majority of the VFAs and phenolic compounds in this fraction are rapidly biodegraded to CH_4 and CO_2 after approximately 1000 m of travel. Those recalcitrant compounds remaining are most likely diluted to below detection levels by the time the ground water reaches the Menominee River.

Dear Mr. Miller and Mr. Musgrove:

SUBJECT: Ford Motor Company/Kingsford Products Site, Dickinson County
MDEQ's Dioxin Analytical Results

The Michigan Department of Environmental Quality (MDEQ) has reviewed the May 2000 groundwater dioxin analytical results from the Ford Motor Company/Kingsford Products (FORD/KPC) Site. From the data, total toxic equivalent concentrations (TECs) have been calculated according to procedures outlined in Rule 323.1209 of Part 31, Water Resources Protection, of the Natural Resources and Environmental Protection Act, 1994 PA 451, as amended. TEC calculations for the total data are attached. The TEC calculations for the wells along the Menominee River are shown in Table 1.

Table 1: Total TECs for monitoring wells GM-5, GM-25-B, GM-26-A, and GM-26-C at the Ford-Kingsford/Easton Estates site, May 2000.

OCDF	**0.000124**	---	---	---
TOTAL TECs (pg/l)	0.595124	0.000043	0	0.0152

Total TECs were compared, in accordance with Rule 323.1209, to the water quality standard of 0.0031 picograms per liter (pg/l), the applicable groundwater-surface water interface (GSI) criteria. Total TECs at monitoring wells GM-5 and GM-26-C exceed the generic GSI criteria. Additional investigation is necessary to confirm and define the extent of the dioxin contamination along the Menominee River. The maximum concentrations and the discharge rate of the venting groundwater, including dioxin, the ambient water concentrations, fish tissue concentrations, and other potential sources of dioxin and furan congeners to the receiving waters must be determined to include in a mixing zone calculation.

In FORD/KPC's August 22, 2000 letter to Mr. Christopher Austin, a number of concerns about the integrity of the MDEQ's groundwater dioxin analyses results were expressed.

These concerns included the MDEQ's sampling techniques and sampling rates. Monitoring wells (MWs) GM-25-B, GM-26-A, and GM-26-C were sampled using the technique described in U.S. Environmental Protection Agency's "Low-Flow (Minimal Drawdown) Ground-Water Sampling Procedure," Groundwater Issue, April 1996. The remaining MWs, GM-2-B, GM-15, and GM-5, were sampled using a submersible groundwater-sampling pump set at the lowest flow rate possible. Since the concentrations found from well GM-5 were at maximum GSI exceedence, it would be advisable to resample the well using a low-flow technique.

FORD/KPC indicated that the reported groundwater results might actually represent dioxin partitioned onto soil, rather than dioxin dissolved in groundwater. The MDEQ's records indicate that only the sample collected from MW GM-2B contained perceptible sediment. In addition, it is unlikely that dioxins/furans were present in the depositional environment that resulted in the formation of this aquifer.

FORD/KPC noted that some sampling equipment encountered the ground surface, and postulated this may have introduced "artifact" concentrations of dioxins into the groundwater samples. The MDEQ's records show that no sampling equipment that contacted the samples touched the ground. Sampling equipment which does not

contact the sample (i.e. the peristaltic pump, the wheels on the pump, and the cooler used to ship the samples) likely contacted the ground. During mobilization to a sampling location, this can not be avoided in any practical sense, and contact of this equipment with the ground would not affect the analytical results of the samples.

A final concern expressed in the letter regarded the possibility of cross contamination affecting sample analyses results. A blank was collected before sampling any MW to determine whether the pump could have contaminated the sample. The data for these pump blanks show that cross contamination did not cause the dioxin detections in the groundwater samples. Additionally, these MWs were sampled in the order of least contaminated to most contaminated, based on concentrations of other compounds (non-dioxin/furan) detected in previous sampling events. The analytic results from this sampling event indicate that these MWs were indeed sampled in the order of least to most contaminated (with dioxins/furans). The appropriate selection of MW sampling order and the analyses of pump blanks demonstrate that dioxins detected in groundwater samples can not be attributed to cross contamination.

If you have any questions or comments, please contact Mr. Austin at 906-875-2071, or you may contact me.

Sincerely,

Andrew W. Hogarth, Assistant Chief
Environmental Response Division

Kingsford Study Area, Kingsford, Michigan
Response to MDEQ March 7, 2001 Letter

Dear Mr. Austin:

ARCADIS G&M reviewed the Michigan Department of Environmental Quality (MDEQ) letter dated March 7, 2001 discussing dioxin/furan data as well as the raw data collected for the above-referenced site. The purpose of this letter is to respond to the MDEQ letter.

The MDEQ letter states that two well samples, from Monitoring Wells GM-25B and GM-26C, show exceedances of dioxin/furan toxicity equivalence concentration (TEC) generic groundwater/surface water interface (GSI) criteria and that additional investigation is needed. ARCADIS G&M has data for a much larger number of wells, including the four referenced in the MDEQ letter, totaling 31 wells. We believe that additional data is not required because no exceedances occur for the entire database, as explained in the letter.

The first matter we would like to address is the evaluation of the dioxin/furan data with respect to results that are found below the detection limit. The MDEQ guidance document, Operational Memorandum #6 Revision 6 (January 12, 2001) specifies that when cleanup criteria do not exceed background or Target Detection Limits (TDLs) then either the background level or the TDLs become the cleanup criteria for purposes of § 20a(11) of Part 201 and for establishing limits for response actions. If the reported analytical results are below the TDLs, then the samples are in compliance with the cleanup criteria.

The second matter we would like to address relates to the appropriate analytical method to use. Operational Memorandum #6 indicates that either of two analytical methods is appropriate for dioxin/furan analysis: Method 8290 or 1613. Method 8290 is from SW-846 and is typically used for waste analysis. Method 1613 is from 40 CFR Part 136 and is used for water analysis. Table 1 of Operational Memorandum #6 specifies the TDLs to be used for dioxin/furan analysis: 10 parts

per quadrillion (ppq) for 2,3,7,8-tetrachlorodibenzodioxin (2,3,7,8-TCDD) and 2,3,7,8-tetrachlorodibenzofuran (2,3,7,8-TCDF), 50 ppq for the penta-, hexa-, and hepta-isomers and 100 ppq for the octa-isomers regardless of which method is used. These detection limits are appropriate for Method 1613 and are the Minimum Level (ML) as well as the TDLs. Method 8290 itself does not actually specify any TDLs. Operational Memorandum #6 Revision 6 uses the 10, 50, and 100 where either analytical method is used. When an analytical result is less than the TDL, that data point is to be used as a zero in the TEC calculation. This approach is consistent with the specific methodology now placed in NPDES permits by MDEQ for polychlorinated biphenyls (PCBs). Dioxins and furans are no different for that purpose.

MDEQ Rule 721 provides that, if the cleanup criterion is below the Practical Quantification Level (PQL), a sample with a result below the MDL shall be considered to have achieved the cleanup criterion. Rule 721 is a carry over from the Michigan Environmental Response Act before Part 201 was enacted, so its terminology is dated, but when read together with Operational Memorandum #6, Revision 6, it is clear that an analytical result below the TDL is in compliance with cleanup criteria.

If a constituent was not detected above the TDL, it was assigned a value of zero. If the constituent was detected in a sample above the TDL, then the detected concentration was used in the TEC calculation. The results of the data evaluation are shown in Table 1.

There are no wells exceeding any generic GSI criteria (regardless of the location of the compliance point and ignoring the use of a mixing zone). Thirty of 31 wells have a TEC of zero. One well, GWGM-68 has a non-zero TEC that is below the generic GSI criterion. The data for GMGW-68 are of questionable quality due to contamination in the blank (see Table 1). The MDEQ March 7, 2001 letter stated that GM-5 and GM-26C exceed generic GSI criteria. That is not the case. No wells exceed generic GSI criteria because the reported data are below TDLs and thus would become zero or the results of the TEC calculation indicate that the result is below the GSI criterion.

The Part 31 rules also deal with the situation where a water quality based effluent limit (WQBEL) is less than the quantification level. Rule 1213 specifies that the analytical method to be used for water is the analytical method specified in 40 CFR Part 136. Where a sample analytical result is less than the quantification level, the sample is considered to be in compliance. Rule 1213(1)(c) provides that the quantification level shall be the ML specified in 40 CFR Part 136. When Rule 1213 went into effect, the Part 136 analytical method (then Method 613) had a MDL of 0.002 micrograms per liter, or 2 parts per trillion. Two parts per trillion is actually

the currently applicable MDL under Rule 1213 because that rule remains unchanged. Since then, U.S. EPA amended Part 136 to add Method 1613 for Clean Water Act analytical use. Method 1613 specifies an ML of 10 ppq for 2,3,7,8-TCDD and 2,3,7,8-TCDF; 50 ppq for the penta-, hexa-, and hepta-isomers; and 100 ppq for the octa-isomers. Note that 40 CFR Part 136 does not contain Method 8290.

When the entire database of 31 well samples is properly evaluated under Part 201, Part 31, Operational Memorandum #6, Revision #6, the Part 31 and Part 201 rules and the MDEQ policy regarding calculating with analytical results below the quantification level, the conclusion to be drawn is that no further action is necessary or appropriate with respect to dioxins and furans.

Very Truly Yours

7123 West 65th Street
Chicago, Illinois 60638

Dear Messrs. Miller and Musgrove:

SUBJECT: Ford/Kingsford Study Area

The purpose of this letter is to specify monitoring that must be completed to initially characterize the Ford/Kingsford site groundwater (treated or raw) that is discharging to the Iron Mountain/Kingsford wastewater treatment plant (WWTP) as part of a preliminary treatability assessment. The characterization sampling addressed by this letter is for polychlorinated dibenzo-p-dioxins (dioxins) and polychlorinated dibenzofurans (furans). Some dioxin and furan sampling of the groundwater has occurred to date but the data reported to the Michigan Department of Environmental Quality (MDEQ) are inadequate to assess potential effects on the WWTP or its discharge. The dioxin and furan data reported to the MDEQ has been noted as below the target level of detection (BTDL). As part of the additional characterization sampling specified below, the actual laboratory analytical results must be provided to the MDEQ in compliance with Part II, Section C. 10 and 11 of the National Pollutant Discharge Elimination System (NPDES) permit number MI0023205 issued to the Iron Mountain/Kingsford Wastewater Treatment Plant.

Dioxin and furan congener monitoring shall be accomplished by analysis of 24-hour composite samples which, at a minimum, shall be comprised of at least three discreet portions collected at approximately evenly spaced intervals during a 24 hour period. Dioxin and furan congener sampling, handling, and analyses shall be conducted according to EPA Method 1613. A minimum of ten Phase II effluent samples will be needed to assess the discharge directed to the WWTP. Also, a minimum of five Phase II influent samples will be required. The ten effluent samples shall be collected to correspond to the respective influent samples (i.e., the effluent samples will be collected a period of time, equivalent to the treatment residence time, after the influent samples were collected). Collection of the five influent samples shall be evenly distributed over the sampling period (i.e., corresponding to every second effluent sample). At a minimum, the current Method 1613 congener specific quantification levels (i.e., minimum levels) for the 17 dioxin and furan congeners listed in Method 1613 (see Attachment A) shall be achieved unless higher levels are appropriate because of sample matrix interference. The basis for any elevated quantification levels must be explained in the reporting of the data for each sample.

The reporting of the data for each sample shall include:

- congener specific detection levels,
- congener specific quantification levels,
- all analytical data for congeners that are detected at or above the respective detection level but below the respective quantification level.

- all analytical data for congeners that are detected at or above the respective quantification level.
- blank and spike information or quality assurance summaries for each sample as appropriate for accurate interpretation of the sample data.
- the toxicity equivalency concentration for each sample calculated as shown in Attachment A.

The data for the 15 samples shall be individually presented and summarized in a final report submitted to Clifton Clark, Marquette District Supervisor of the Environmental Response Division (ERD) by February 28, 2001. If the data requirements noted above are available for any previously analyzed Phase II wastewater samples, those samples could be included as part of the set of 15 samples needed to characterize the initial site wastewaters directed to the WWTP.

An estimate of the change or range in the site influent and effluent congener concentrations when the more contaminated wells are included in the pumping regime shall be included in the final report. A dioxin and furan headworks analyses to assess potential effects on the WWTP effluent and sludge shall also be included in this report.

Please notify Mr. Clark by November 14, 2001, of your intended schedule for implementation of the dioxin and furan congener monitoring as described above. If this monitoring is not initiated by the Ford Motor Company and The Kingsford Products Company by November 28, 2001, the ERD intends to proceed with the monitoring.

As stated in previous letters, the state continues to incur costs associated with this facility and interest continues to accrue. Any expenditure of public funds and accumulated interest for this purpose is subject to cost recovery actions by the state pursuant to state law, Section 20126a of Part 201, Environmental Remediation, of the Natural Resources and Environmental Protection Act, 1994 PA 451, as amended.

Please be aware that additional chemical characterization, headworks analyses, and reporting may be necessary for later phases of the site cleanup. If you have any questions regarding these monitoring needs, please feel free to contact us.

Sincerely,

for Steven Casey

Subject:
Response to MDEQ November 4, 2001 Letter Regarding Dioxin Characterization of Groundwater Discharge from Phase II of the Pilot Test, Ford/Kingsford Site, Kingsford, Michigan.
ARCADIS G&M Project No. WI000925.0021

Tampa, Florida
11 December 2001

Contact:
Jim Bedessem

Direct Dial:
813 264 3402

Dear Messrs. Clark and Casey:

On behalf of Ford Motor Company (Ford) and The Kingsford Products Company (Kingsford), ARCADIS G&M, Inc. (ARCADIS) is responding to the MDEQ letter dated November 4, 2001 to Mr. David Miller of Ford and Mr. Daniel Musgrove of Kingsford. In the November 4, 2001 letter, the MDEQ stated that Ford and Kingsford must complete an initial polychlorinated dibenzo-p-dioxin (dioxins) and polychlorinated dibenzofuran (furans) characterization of the site groundwater being discharged to the Iron Mountain/Kingsford wastewater treatment plant (WWTP) as part of a preliminary treatability assessment.

Provided below is a summary of the items stated in the November 4, 2001 letter and our response. For ease of review, each item is provided in italics format followed by our response in regular font.

Collect ten effluent and five influent samples of Phase II groundwater and have the samples analyzed for polychlorinated dibenzo-p-dioxins (dioxins) and polychlorinated dibenzofurans (furans).

Response: Ford and Kingsford sampled the groundwater discharge to the WWTP for dioxins and furans. During Phase I, a total of six effluent and two influent samples were collected and submitted for laboratory analysis of dioxins and furans. Through November 2001, a total of four effluent and three influent samples (one sample from each of the three wells being pumped) have been collected from Phase II and submitted for laboratory analysis of dioxins and furans.

While we feel that the Phase I samples are appropriate for use in this study because the water that was extracted, pretreated, and discharged in Phase I also comprises 50

2.6.1 - 12/11/01

percent of the flow in Phase II, we will comply with MDEQ's request to collect a total of ten effluent and five influent samples from Phase II under the following conditions. To achieve the reporting requirements requested by MDEQ, the additional dioxin and furan samples must be collected (beyond the previously approved sampling protocol for the Phase I and Phase II discharge) and submitted for laboratory analysis prior to the end of December 2001. By complying with this additional request from the MDEQ, and due to the fact that Phase II already incorporates pumping the most impacted well along the river, no additional dioxin and furan analyses/evaluations will be conducted for the remainder of the remedial activities unless this additional dioxin and furan monitoring and evaluation shows that the Phase II discharge will have an adverse effect on the WWTP effluent and sludge.

Samples should be 24-hour composites comprised of at least three discreet portions collected at approximately evenly spaced intervals during a 24-hour period.

Response: The MDEQ-approved monitoring plans that have been followed during Phase I and Phase II did not require collection of composite samples and the samples collected to date are grab samples. It is our intent to continue to collect grab samples rather than composite samples for the reasons explained below.

The collection of composite samples is not necessary to provide representative samples from the pretreatment systems – particularly the Phase II system. The Phase II pretreatment system consists of two complete-mix biological reactors and a single clarifier. The residence time through the complete-mix biological reactors at the average Phase II flowrate of 45 gallons per minute (gpm) is approximately 1 day, and the clarifier provides approximately 8 additional hours of residence time. The complete-mix nature of the biological reactors and the residence time through the entire system results in effluent samples that will not have substantial changes in concentrations throughout a 1-day period and therefore, compositing is unnecessary.

With respect to the influent samples, compositing of those samples is also unnecessary to generate representative samples. The influent samples are being collected from the individual wells contributing flow to the Phase II system. Constituent concentrations do not change significantly over the course of a day, but change gradually over several months to several years depending on the aquifer formation and plume characteristics. Therefore, composite samples are not warranted.

Dioxin and furan congener sampling, handling, and analyses shall be conducted according to EPA Method 1613....At a minimum, the current Method 1613 congener specific quantification levels (i.e., minimum levels) for the 17 dioxin and furan congeners listed in Method 1613 shall be achieved unless higher levels are appropriate because of sample matrix interference.

Response: As discussed in previous correspondence dated August 7, 2001 to the MDEQ Environmental Response Division, MDEQ Operational Memorandum #6

indicates that either of two analytical methods is appropriate for dioxin/furan analysis: EPA Methods 8290 or 1613. EPA Method 8290 is from SW-846 and is typically used for waste analysis. EPA Method 1613 is from 40 CFR Part 136 and is used for water analysis. In my call with Ron Raisanen on November 13, 2001, I indicated that the analytical method we have been using for the existing Phase I and Phase II dioxin and furan analyses may not be EPA Method 1613 and he indicated that this was acceptable as long as the desired quantification levels were achieved.

The samples collected during Phases I and II (listed above) have been analyzed using EPA Method 8290, and the desired quantification levels have been achieved. It is our intent at this time to continue to use EPA Method 8290 for dioxin and furan analysis for the remainder of the study.

The actual laboratory analytical results must be provided to the MDEQ.

Response: The actual laboratory analytical results will be provided to the MDEQ. We would like to point out that as part of the Phase I and Phase II discharge approval process, Ford and Kingsford agreed to specific monitoring plans to be implemented during the Phase I and Phase II pilot study, and as part of the reporting to provide the actual laboratory results for the monitoring that was done. The laboratory results for the Phase I and Phase II monitoring have been provided as they became available and after the data were validated, in the monthly reports to the WWTP and the MDEQ.

The reporting of the data for each sample shall include:

- *Congener specific detection levels.*
- *Congener specific quantification levels.*
- *All analytical data for congeners that are detected at or above the respective detection level but below the respective quantification level.*
- *All analytical data for congeners that are detected at or above the respective quantification level.*
- *Blank and spike information or quality assurance summaries for each sample as appropriate for accurate interpretation of the sample data.*
- *The toxicity equivalency concentration for each sample calculated as shown in Attachment A.*

Response: As discussed in previous correspondence dated August 7, 2001 to the MDEQ Environmental Response Division, Ford and Kingsford do not concur with a portion of the calculation approach described in Attachment A to the November 4, 2001 letter and will continue to calculate and report the dioxin and furan toxicity equivalency concentrations in accordance with our August 7, 2001 letter.

As indicated in the previous response, the actual laboratory results will be provided to the MDEQ.

An estimate of the change or range in concentration in the site influent and effluent congener concentrations when the more contaminated wells are included in the pumping regime shall be included in the final report. A dioxin and furan headworks

ARCADIS GERAGHTY & MILLER

analysis to assess the potential effects on the WWTP effluent and sludge shall also be included in this report.

Response: The estimate and headworks analysis will be included in the report.

Requirement: *Schedule requirements include monitoring be initiated by November 28, 2001 and a final report submitted by February 28, 2002.*

Response: As indicated previously, this monitoring is already underway and the last samples will be collected in December 2001. A preliminary report providing the data generated through October 2001 will be provided to the MDEQ in December 2001 and the final report with complete analyses will be provided by February 28, 2002.

If you have any questions regarding this response letter or our implementation plans, please contact me at the number listed above.

Sincerely,

ARCADIS G&M, Inc.

Direct Dial:
813 264 3402

Dear Messrs. Clark and Casey:

On behalf of Ford Motor Company (Ford) and The Kingsford Products Company (Kingsford), ARCADIS G&M, Inc. (ARCADIS) is providing a submittal of polychlorinated dibenzo-p-dioxin (dioxins) and polychlorinated dibenzofuran (furans) data gathered through October 2001 as part of the requested characterization of groundwater being discharged from Phase II of the Pilot Test. This data includes three Phase II effluent samples as well as background data from samples of the wastewater treatment plant influent and digested sludge. Also included are five Phase I effluent and one Phase I influent sample. Included with this letter are the following:

- Tabulated data with toxicity equivalents calculated.
- Laboratory data packages.

As shown in the tabulated data summary, the analysis of the samples collected to date have successfully met the minimum levels as requested in your November 4, 2001 letter and no concentrations of dioxins or furans above the specified congener-specific quantification levels have been detected.

The requested headworks analysis will be provided following the completion of the remaining characterization sampling and provided with the final report at the end of February 2002.

1.6.1 - 12/27/01_2

If you have any questions regarding the information provided with this letter, please contact me at the number listed above.

Sincerely,

ARCADIS G&M, Inc.

ENVIRONMENT

Subject:
Dioxin Characterization of Groundwater Discharge from Phase II of the Pilot Test, Ford/Kingsford Site, Kingsford, Michigan.
ARCADIS G&M Project No. WI000950.0021

Tampa, Florida
27 February 2002

Contact:
Jim Bedessem

Direct Dial:
813 264 3402

Dear Messrs. Clark and Casey:

On behalf of Ford Motor Company (Ford) and The Kingsford Products Company (Kingsford), ARCADIS is providing this final submittal of polychlorinated dibenzo-p-dioxin (dioxins) and polychlorinated dibenzofuran (furans) data gathered as part of the requested characterization of groundwater being discharged from Phase II of the Pilot Test, as well as previous dioxin and furan data collected during Phase I of the Pilot Test. This data has been organized as requested in the letter from Ron Raisenan dated February 5, 2002, and is presented in tabular format as follows:

Table 1. Summary of Samples Collected as Part of the Pilot Test.
Table 2. Phase I Influent Sample Results.
Table 3. Phase I Effluent Sample Results.
Table 4. Phase II Influent Sample Results.
Table 5. Phase II Effluent Sample Results.
Table 6. Wastewater Treatment Plant Sample Results.

As discussed in previous correspondence to the Michigan Department of Environmental Quality (MDEQ) (letters dated August 7, 2001 and December 11, 2001), Ford and Kingsford do not concur with a portion of the calculation approach described in Attachment A to your November 4, 2001 letter. Therefore, while the data has now been organized so that the presentation is more consistent with the format requested in the February 5, 2002 letter from Ron Raisenan, we have still calculated and presented the dioxin and furan toxicity equivalent concentrations in accordance with our August 7, 2001 letter.

As agreed to in our response letter dated December 11, 2001, also included with this data transmittal are the complete laboratory data packages for the samples collected since October 31, 2001. The laboratory data packages for samples collected prior to this date were previously transmitted to the MDEQ in a letter dated December 27,

2.6.1 – 2/27/02

2001, with the exception of the data packages for samples collected on August 15, 2001, which are included with this transmittal.

As shown in the tabulated data summary, the analysis of the samples collected successfully met the quantification levels as requested in your November 4, 2001 letter, and no concentrations of dioxins or furans above the specified congener-specific quantification levels have been found in either the influent or effluent samples from Phase I or Phase II. This includes five samples from Extraction Well GMEW-3 which has the highest concentration of constituents in groundwater along the river as measured by the chemical oxygen demand (COD). Based on these data, the dioxin and furan congener concentrations in the influent and effluent are not expected to be present above specified congener-specific quantification levels even if more wells are included in the pumping regime in the future.

The November 4, 2001 letter also requested a headworks analysis to assess the potential effects on the Wastewater Treatment Plant (WWTP) effluent and sludge. The discharge from the groundwater system will not have an adverse effect on the WWTP effluent or sludge because dioxins or furans above specified congener-specific quantitation levels are not currently discharged and are not expected to be discharged in the future even if more wells are added to the pumping regime. A headworks analysis is not necessary because the water from the pretreatment system is below congener-specific quantitation levels and therefore any headworks calculations would only show that the groundwater flow from the pretreatment system dilutes the dioxin and furan concentrations previously observed at the WWTP.

Finally, as indicated in our December 11, 2001 response letter, since no dioxins or furans above the specified congener-specific quantification levels were found in either the influent or effluent during this requested study, and it was demonstrated that no adverse impacts to the WWTP effluent or sludge are expected, no additional dioxin and furan analyses/evaluations will be conducted during the remainder of the remedial activities.

If you have any questions regarding the information provided with this letter, please contact me at the number listed above.

Sincerely,

ARCADIS G&M, Inc.

BEF Bioaccumulation equivalency factor [MDEQ, Rule 323.1209(4)(ii)].
BQL Result was below the QL; contribution to the TEC is zero.
ppq Parts per quadrillion (picograms per liter).
QL Congener quantification level (ppq).
TEC Toxicity equivalence concentration of 2,3,7,8-TCDD.
TEF Toxicity equivalency factor [MDEQ, Rule 323.1209(4)(ii)].

* TEC (ppq) = Detected result (ppq) × BEF × TEF

Dear Jim:

SUBJECT: Dioxin Characterization Phase II

This is a reply to your December 11, 2001 letter of response to the Michigan Department of Environmental Quality's (DEQ) November 4, 2001 letter. Your December 11, 2001 letter was submitted in response to MDEQ's letter which requested, in part, characterization of contaminated ground waters for polychlorinated dibenzo-p-dioxins (PCDD) and polychlorinated dibenzofurans (PCDF) and specified some sampling and reporting details. Our response will be in the same order as your responses, which are italicized.

Response: *Ford and Kingsford sampled the groundwater discharge to the WWTP for dioxins and furans. During Phase I, a total of six effluent and two influent samples were collected and submitted for laboratory analysis of dioxins and furans. Through November 2001, a total of four effluent and three influent samples (one sample from each of the three wells being pumped) have been collected from Phase II and submitted for laboratory analysis of dioxins and furans.*

While we feel that the Phase I samples are appropriate for use in this study because the water that was extracted, pretreated, and discharged in Phase I also comprises 50 percent of the flow in Phase II, we will comply with DEQ's requirement to collect a total of ten effluent and five influent samples from Phase II under the following conditions. To achieve the reporting requirements requested by DEQ, the additional dioxin and furan samples must be collected (beyond the previously approved sampling protocol for the Phase I and Phase II discharge) and submitted for laboratory analysis prior to the end of December 2001. By complying with this additional request from the DEQ, and due to the fact that Phase II already incorporates pumping the most impacted well along the river, no additional dioxin and furan analyses/evaluations will be conducted for the remainder of the remedial activities unless this additional dioxin and furan monitoring and evaluation shows that the Phase II discharge will have an adverse effect on the WWTP effluent and sludge.

DEQ response:

We can agree to the use of individual well sample data as influent data if all the well data collected on a particular day are to be considered to represent one influent sample for which there is a corresponding effluent sample. For example, the data from three well samples collected on a Thursday (or other appropriate short time window) from three different wells may be used to represent the influent character for an effluent sample collected the next day on Friday (this approximates the Phase II detention time) and those three samples will be considered one of the requested five influent samples.

Although the Phase II Operating Procedures, which were approved by the DEQ included dioxin and furan sampling, the data provided was not considered sufficient to evaluate potential effluent quality (PEQ). The additional Dioxin and Furan sampling requested in the DEQ Nov. 4, 2001 letter should cover the sampling requirements of the Phase II Operating Procedures unless it is shown that accepting the Phase II effluent poses a problem for the Iron Mountain/Kingsford WWTP. The MDEQ reserves the right to require additional PCDD/PCDF sampling based on its review of the available database and the evaluation of potential effluent quality. The water quality-based limits for PCDD/PCDF are well below detection and quantification levels and as such require the DEQ to consider all data and potential effects in the evaluation of the need for monitoring and/or limit conditions relative to the regulation of an NPDES permit. In this instance, imposing a requirement for additional characterization work is not limited to a scenario founded only on the presence of quantifiable PCDD/PCDF congeners in the WWTP effluent. Additionally, your letter notes that the source water character could change over a period of time and this issue may support the need for additional future monitoring. We wish to emphasize that in NPDES programs, the interpretation or use of data for some chemicals can differ between a compliance and a monitoring mode and also when deciding the need for water quality based effluent conditions in a NPDES permit.

Response: *The DEQ-approved monitoring plans that have been followed during Phase I and Phase II did not require collection of composite samples and the samples collected to date are grab samples. It is our intent to continue to collect grab samples rather than composite samples for the reasons explained below.*

The collection of composite samples is not necessary to provide representative samples from the pretreatment systems – particularly the Phase II system. The Phase II pretreatment system consists of two complete-mix biological reactors and a single clarifier. The residence time through the complete-mix biological reactors at the average Phase II flowrate of 45 gallons per minute (gpm) is approximately 1 day, and the clarifier provides approximately 8 additional hours of residence time. The complete-mix nature of the biological reactors and the residence time through the entire system results in effluent samples that will not have substantial changes in concentrations throughout a 1-day period and therefore, compositing is unnecessary.

With respect to the influent samples, compositing of those samples is also unnecessary to generate representative samples. The influent samples are being collected from the individual wells contributing flow to the Phase II system. Constituent concentrations do not change significantly over the course of a day, but change gradually over several

months to several years depending on the aquifer formation and plume characteristics. Therefore, composite samples are not warranted.

DEQ response:
We concur that grab sampling is appropriate as long as effluent samples correspond temporally to influent samples.

Response: *As discussed in previous correspondence dated August 7, 2001 to the MDEQ Environmental Response Division, DEQ Operational Memorandum #6 indicates that either of two analytical methods is appropriate for dioxin/furan analysis: EPA Methods 8290 or 1613. EPA Method 8290 is from SW-846 and is typically used for waste analysis. EPA Method 1613 is from 40 CFR Part 136 and is used for water analysis. In my call with Ron Raisanen on November 13, 2001, I indicated that the analytical method we have been using for the existing Phase I and Phase II dioxin and furan analyses may not be EPA Method 1613 and he indicated that this was acceptable as long as the desired quantification levels were achieved.*

The samples collected thus far during Phases I and II (listed above) have been analyzed using EPA Method 8290, and the desired quantification levels have been achieved. It is our intent at this time to continue to use EPA Method 8290 for dioxin and furan analysis for the remainder of the study.

DEQ response:
We can agree to the use of EPA method 8290 for analyses of the Phase II influent and effluent samples; however, if monitoring is required at the WWTP based on our review of the available database, EPA method 1613 must be used as required by the NPDES program.

Response: *The actual laboratory analytical results will be provided to the DEQ. We would like to point out that as part of the Phase I and Phase II discharge approval process, Ford and Kingsford agreed to specific monitoring plans to be implemented during the Phase I and Phase II pilot study, and as part of the reporting to provide the actual laboratory results for the monitoring that was done. The laboratory results for the Phase I and Phase II monitoring have been provided as they became available and after the data were validated, in the monthly reports to the WWTP and the DEQ.*

DEQ response:
We agree that laboratory results have been submitted as they have become available.

Response: *As discussed in previous correspondence dated August 7, 2001 to the DEQ Environmental Response Division, Ford and Kingsford do not concur with the calculation approach described in the November 4, 2001 letter and will continue to calculate and report the dioxin and furan toxicity equivalency concentrations in accordance with our August 7, 2001 letter.*

As indicated in the previous response, the actual laboratory results will be provided to the DEQ and will show the detection limits requested by DEQ.

DEQ response:
We wish to emphasize that there are programmatic differences between the Surface Water Quality Division and the Environmental Response Division in the way that data are utilized in some cases. The discharge from the site is now being directed to a NPDES regulated facility. The regulations and rules that govern the NPDES program dictate what data are needed and how those data are utilized in evaluations of PEQ and in developing monitoring or limit conditions for a permitted facility. The TEC calculation method specified in Attachment A of the DEQ November 4, 2001 letter is consistent with those rules and regulations and will be used in assessing potential effects from the Ford Kingsford site.

Response: *The estimate and headworks analysis will be included in the report.*

DEQ response:
The submittal of a headworks analysis will be adequate.

Response: As indicated previously, this monitoring is already underway and the last samples will be collected in December 2001. A preliminary report providing the data generated through October 2001 will be provided to the MDEQ in December 2001 and the final report with complete analyses will be provided by February 28, 2002.

DEQ response:
We have received the preliminary report.

If you have any questions, feel free to contact Ron Raisanen, Chris Austin or ourselves at any time.

Sincerely,

Steve Casey

ENVIRONMENTAL

Subject:
Dioxin Characterization of Groundwater Discharge from Phase II of the Pilot Test, Ford/Kingsford Site, Kingsford, Michigan.
ARCADIS G&M Project No. WI000925.0021

Tampa, Florida
29 March 2002

Contact:
Jim Bedessem

Direct Dial:
813 264 3402

Dear Messrs. Clark and Casey:

On behalf of Ford Motor Company (Ford) and The Kingsford Products Company (Kingsford), ARCADIS G&M, Inc. (ARCADIS) is providing this submittal of polychlorinated dibenzo-p-dioxin (dioxins) and polychlorinated dibenzofuran (furans) data. This submittal presents the data and toxicity equivalent concentration calculations in the format requested by the MDEQ. However, as discussed in previous correspondence to the MDEQ (letters dated August 7, 2001, December 11, 2001, and February 27, 2002), Ford and Kingsford still do not concur with a portion of the calculation approach described in Attachment A to the November 4, 2001 letter from the MDEQ to Ford and Kingsford. Therefore, we are providing two sets of tabulated data, one set with dioxin and furan toxicity equivalent concentrations calculated in accordance with our August 7, 2001 letter (Attachment 1) and one set calculated as requested in MDEQ's November 4, 2001 letter (Attachment 2). It should be noted that nearly all detections, particularly those detections at concentrations between the detection limit (DL) and the quantification level (QL), are estimated or otherwise qualified results.

Each set of data is presented in tabular format as follows:

Table 1. Summary of Samples Collected as Part of the Pilot Test.
Table 2. Phase I Influent Sample Results.
Table 3. Phase I Effluent Sample Results.
Table 4. Phase II Influent Sample Results.
Table 5. Phase II Effluent Sample Results.
Table 6. Wastewater Treatment Plant Sample Results.

The laboratory data packages have previously been transmitted to the MDEQ, therefore this submission includes only the tabulated data.

ARCADIS

If you have any questions regarding the information provided with this letter, please contact me at the number listed above.

Sincerely,

ARCADIS G&M, Inc.

James M. Bedessem, P.E.
Principal Engineer

(ND) Detected result was qualified as "not detected" due to associated blank contamination; contribution to the TEC is zero.

BEF Bioaccumulation equivalency factor [MDEQ, Rule 323.1209(4)(ii)].

DL Detection limit.

ppq Parts per quadrillion (picograms per liter).

NA Information is not available.

ND Congener was not detected; contribution to the TEC is zero.

QL Congener quantifical limit for that sample.

TEC Toxicity equivalence concentration of 2,3,7,8-TCDD.

TEF Toxicity equivalency factor [MDEQ, Rule 323.1209(4)(ii)].

* TEC (ppq) = Detected result (ppq) × BEF × TEF

Data Qualifiers:

B – Compound was detected in the associated QC method blank sample.

E – Estimated maximum possible concentration.

J – Concentration is qualified as estimated.

(ND) Detected result was qualified as "not detected" due to associated blank contamination; contribution to the TEC is zero.

BEF Bioaccumulation equivalency factor [MDEQ, Rule 323.1209(4)(ii)].

DL Detection limit.

ppq Parts per quadrillion (picograms per liter).

NA Information is not available.

ND Congener was not detected; contribution to the TEC is zero.

QL Congener quantifical limit for that sample.

TEC Toxicity equivalence concentration of 2,3,7,8-TCDD.

TEF Toxicity equivalency factor [MDEQ, Rule 323.1209(4)(ii)].

* TEC (ppq) = Detected result (ppq) × BEF × TEF

Data Qualifiers:

B – Compound was detected in the associated QC method blank sample.

E – Estimated maximum possible concentration.

J – Concentration is qualified as estimated.

Mr. Brian Brady
Surface Water Quality Division
Michigan Department of Environmental Quality
420 5th Street
Gwinn, Michigan 49841

Subject:
Dioxin Sampling Schedule for the Iron Mountain/Kingsford Wastewater Treatment Plant (IMKWWTP).

Dear Mr. Brady:

As we discussed at our meeting on November 12, 2002, we believe the effluent sampling plan proposed in our August 1, 2002 letter will allow the determination of the following:

1. The current Phase II effluent dioxin concentrations at the IMKWWTP.
2. The potential effects on the IMKWWTP effluent dioxin concentrations due to the Phase III effluent discharge.

Three samples over three months (1 sample per month) will be collected to evaluate whether any dioxin congeners are detectable in the IMKWWTP effluent. Composite samples will be collected and analyzed using United States Environmental Protection Agency (USEPA) Method 1613. This effluent data, along with the previously collected sludge data, influent data, and Phase I and II groundwater influent and effluent data, will be used to perform the requested dioxin headworks analysis for the Phase III discharge.

The schedule for this sampling and subsequent evaluation will be as follows:

August 1, 2002	Proposal submitted to MDEQ
October 15, 2002	MDEQ acceptance of proposal
January 22, 2002	Sampling event 1
February 11, 2003	Sampling event 2
March 10, 2003	Sampling event 3
May 30, 2002	Submittal of Sampling Report, Determination in accordance with R323.1211, and Headworks Analysis

The sampling will be coordinated with ARCADIS to ensure that the groundwater discharge remains generally consistent (in terms of percentage of flow from the various extraction wells included in the pilot test) from event to event.

If you have any questions regarding the proposed schedule, please contact me at 906-774-2255.

Sincerely,

Gary Lessard, Superintendent
Iron Mountain/Kingsford Wastewater Treatment Plant

(ND) Detected result was qualified as "not detected" due to associated blank contamination; contribution to the TEC is zero.

BEF Bioaccumulation equivalency factor [MDEQ, Rule 323.1209(4)(ii)].

DL Detection limit.

NA Information is not available.

ND Congener was not detected; contribution to the TEC is zero.

ppq Parts per quadrillion (picograms per liter).

QL Congener quantification level.

TEC Toxicity equivalence concentration of 2,3,7,8-TCDD.

TEF Toxicity equivalency factor [MDEQ, Rule 323.1209(4)(ii)].

* TEC (ppq) = Detected result (ppq) × BEF × TEF

Data Qualifiers:

B – Compound was detected in the associated QC method blank samp

E – Estimated maximum possible concentration.

J – Concentration is qualified as estimated.

K – Concentration exceeds the calibration curve; qualified as estimated.

U – Result was qualified as "not detected" during data validation.

Q – Estimated maximum possible concentration.

NA Information is not available.

ND Congener was not detected; contribution to the TEC is zero.

ppq Parts per quadrillion (picograms per liter).

QL Congener quantifical limit for that sample.

TEC Toxicity equivalence concentration of 2,3,7,8-TCDD.

TEF Toxicity equivalency factor [MDEQ, Rule 323.1209(4)(ii)].

* TEC (ppq) = Detected result (ppq) x BEF x TEF

Data Qualifiers:

B – Compound was detected in the associated QC method blank sample.

E – Estimated maximum possible concentration.

J – Concentration is qualified as estimated.

K – Concentration exceeds the calibration curve; qualified as estimated.

U – Result was qualified as "not detected" during data validation.

Q – Estimated maximum possible concentration.

Subject:
Dioxin Data Validation Samples Collected January 22, 2003, at Kingsford, Michigan

ARCADIS Geraghty & Miller Project No.:
WI000975.0021

This report summarizes the review and evaluation of the January 22, 2003 samples WWTP EFF and PhII EFF collected in Kingsford, Michigan. Samples were submitted to Severn Trent Laboratories (STL), Inc., in Knoxville, Tennessee for the analysis of Polychlorinated Dibenzodioxins (PCDDs) and Polychlorinated Dibenzofurans (PCDFs) using United States Environmental Protection Agency (USEPA) Method 1613 Revision B (USEPA Method 1613B) (October 1994). This method uses high-resolution gas chromatography/high-resolution mass spectrometry (HRGC/HRMS). Samples collected on January 22, 2003 were received by STL on January 24, 2003, and were assigned the STL project number H3A300238.

No field quality control (QC) samples were collected on January 22, 2003 in association with samples WWTP EFF, and PhII EFF. Sample WWTP EFF was a composite of samples collected from three different times. Both the WWTP and PhII samples had a second portion filtered and analyzed. A total of four samples were analyzed. All samples were extracted February 3, 2003 and analyzed on February 11, 2003.

The evaluation of data quality was performed using the guidance documents entitled: "*Data Validation Standard Operating Procedures for Chlorinated Dioxin/Furan Analysis by High-Resolution Gas Chromatography/High-Resolution Mass Spectrometry, USEPA Region IV, Revision 3.0, dated May 2002*," and "*USEPA Analytical Operations/Data Quality Center (AOC) National Functional Guidelines for Chlorinated Dioxin/Furan Data Review dated August 2002*," the method specified criteria from USEPA Method 1613B, and professional judgment.

A detailed evaluation of the associated samples collected January 22, 2003 is presented in the following sections.

1.0 System performance Quality control Review

USEPA Method 1613B requires the use of HRGC/HRMS to detect and quantitate PCDD/PCDF. The high-resolution capillary column DB-5 was used for all analyses. Analytical results were reported to the estimated detection limit (EDL).

1.1 System Performance Check

Each instrument used for USEPA Method 1613B analysis was tuned using calibrant perfluorokerosene (PFK) for mass calibration and mass spectrometer resolution greater than or equal to 10,000, selective ion monitoring (SIM) scan descriptor switching times, and GC resolution. A system performance check was provided for each 12 hour analysis period, and for each instrument used during analysis. HRGC/HRMS instrument MAT95S was used to analyze the field samples and associated batch QC.

1.2 Initial Calibrations

Initial calibrations were reviewed for each of the instruments used for STL Report H3A300238. A five point initial calibration was performed by STL on the instrument. The following initial calibrations were reviewed: 9/12-13/02. The percent relative standard deviations (%RSDs), relative response factors (RRFs), signal to noise (S/N), retention time windows, and ion abundance ratios were reviewed against the method specified criteria. The associated initial calibrations were acceptable.

1.3 Continuing Calibrations

A continuing calibration (mid level standard) was analyzed prior to and following sample analysis. Less than the standard 12 hour analytical period was used. The continuing calibration was reviewed for each instrument RRFs, percent differences (%D), ion-abundance ratios, internal standard, and recovery compound, and was acceptable. The following continuing calibrations were reviewed in association with STL Report H3A300238: t 030211s2 associated with Method Blank, Laboratory Control Sample (LCS), PHII EFF (1/22/03)D, PHII EFF (1/22/03)T, WWTP EFF (1/22/03)T, and WWTP EFF (1/22/03)D. All continuing calibrations associated with STL Report H3A300238 were acceptable.

1.4 Method Blanks

Method blank (FG2X61AA) was extracted with the field samples in STL Report H3A300238. In accordance with the *"Data Validation Standard Operating Procedures for Chlorinated Dioxin/Furan Analysis by High-Resolution Gas Chromatography/High-Resolution Mass Spectrometry, USEPA Region IV, Revision 3.0, dated May 2002,"* and *"USEPA Analytical Operations/Data Quality Center (AOC) National Functional Guidelines for Chlorinated Dioxin/Furan Data Review dated August 2002,"* any target analyte detected in the associated method blank is evaluated against the associated field samples by multiplying the blank concentration by five times (action level). The associated field sample data values reported less than the Action Level are qualified as "U/Not Detected," inclusive of those vales reported at the EDL or estimated maximum possible concentration (EMPC). All values detected in the method blank were less than the target detection limit

(Section 2.3 of this evaluation) and therefore, the method blank is determined to be acceptable. All detected compounds were less than five times the method blank. Therefore, all detected sample compounds for this report should be re-flagged as NOT Detected.

1.5 Rinsate Blanks

A rinsate blank, field QC sample was not collected in associated with samples reported in STL Report H3A300238.

1.6 Matrix Spikes/Matrix Spike Duplicates (MS/MSD)

Additional sample volume of the samples was not supplied for MS/MSD analyses. The analysis of MS/MSD on project related matrices not only provides precision and accuracy data but serves to determine if there are matrix interferences related to the method. Method accuracy was demonstrated though the analysis of an LCS.

1.8 Laboratory Control Sample(LCS)

One LCS (file FG2X61AC) was extracted in association with the field samples analyzed in STL Report H3A300238. All recoveries were reviewed against the in-house control limit criteria for LCS recovery. The LCS accuracy data was acceptable.

1.9 Duplicate Analyses

Additional sample volume of the samples was not supplied for duplicate sample analyses. The samples presented were duplicates with one being filtered and one not. But, because all compounds were considered non-detect, precision cannot be determined.

2.0 Sample Review

STL Report H3A300238 contained samples PHII EFF (1/22/03)D, PHII EFF (1/22/03)T, WWTP EFF (1/22/03)T, and WWTP EFF (1/22/03)D collected on January 22, 2003.

2.1 Holding Time

The chain-of-custody form was properly completed and signed and the groundwater sample was received in good condition and properly preserved at 4 degrees centigrade. The samples were extracted and analyzed within holding times.

2.2 Compound Identification

Sample results were reviewed against the method specific criteria for compound identification. Laboratory performance was acceptable.

All of the detected compounds were lower than five times the method blank detected levels. Therefore, all detected sample compounds were assigned the value NOT Detected.

2.3 Reporting

Target detection limits for USEPA Method 1613B are as follows for aqueous matrix:

≤ 10 picograms per liter (pg/L) TCDD & TCDF
≤ 50 pg/L Pent – Hepta CDD & CDF
≤ 100 pg/L OCDD & OCDF

The laboratory reported EDL, presented on the analytical reports as the detection limit (DL), which represents the maximum possible concentration of a target analyte that could be present without being detected. The EDL was reported for non-detected values less than the method target detection limit and were calculated for each field sample.

2.4 Internal Standards

Fifteen internal standards are required by USEPA Method 1613B. All 15 labeled internals, surrogates, and alternate standards were reviewed against a control limit criteria of 40-130 percent recovery. STL has established in-house criteria. All labeled standards were reviewed for each of the associated field samples and found to be acceptable with the following exceptions:

WWTP EFF (1/22/03) – One internal standard was outside of the lower control limit criteria of 40-135 percent recovery. In accordance with the "*Data Validation Standard Operating Procedures for Chlorinated Dioxin/Furan Analysis by High-Resolution Gas Chromatography/High-Resolution Mass Spectrometry, USEPA Region IV, Revision 3.0, dated May 2002*," criteria, only detected values are qualified as "J/Estimated." Non detected values are qualified when the labeled standard recoveries are less than 10 percent. In this case, all of the labeled standards were less than 40 percent recovery but greater than 10 percent, and all of the associated sample results were non detect; therefore, no qualification was necessary.

3.0 Overall Data Assessment

The evaluation of data quality was performed using the following Guidance documents "*Data Validation Standard Operating Procedures for Chlorinated Dioxin/Furan Analysis by High-Resolution Gas Chromatography/High-Resolution Mass Spectrometry, USEPA Region IV, Revision 3.0, dated May 2002*," and "*USEPA Analytical Operations/Data Quality Center (AOC) National Functional Guidelines for Chlorinated Dioxin/Furan Data Review dated August 2002*," the method specified criteria from USEPA Method 1613B, and professional judgment. The field sample data for STL Report H3A300238 are presented in Attachment A. No data were rejected. All of the detected compounds were lower than five times the method blank detected levels. Therefore all detected sample compounds were assigned the value NOT Detected.

Dear Mr. Saalfeld:

On behalf of Ford Motor Company (Ford) and The Kingsford Products Company (KPC), ARCADIS is providing this submittal of recently collected polychlorinated dibenzo-p-dioxin (dioxin) and polychlorinated dibenzofuran (furan) data.

This data is being collected at the request of the Iron Mountain/Kingsford Joint Sewage Board, and is being done concurrently with data collection on the effluent from the Wastewater Treatment Plant (WWTP). An agreement between the Iron Mountain/Kingford Joint Sewage Board and the MDEQ on that effluent sampling program required only the collection and reporting of 3 months of data on the WWTP effluent.

This submittal presents the recent Phase II effluent data and toxicity equivalent concentration calculations in the format requested by the MDEQ (attached Table 1). However, as discussed in previous correspondence to the MDEQ (letters dated August 7, 2001, December 11, 2001, and February 27, 2002), Ford and KPC still do not concur with a portion of the calculation approach described in Attachment A of the MDEQ letter dated November 4, 2001. The validated data in Table 1 shows that dioxins and furans were not detected in the Phase II effluent and that the detection limits (DL) achieved were below the required quantification levels (QL). While this submittal reports validated data, it should be still be considered "Preliminary" and does not include the laboratory reports. The final report will be sent by the end of May 2003.

In your conversation with Mr. Robinson, you also requested the groundwater data to the Phase II system. This data was provided to the MDEQ in a letter dated March 29, 2002 addressed to Mr. Clifton Clark and Mr. Steve Casey, on which you were copied. The influent data was presented in Tables 2 and 4 attached to the March 29, 2002 letter. We would like to note that the data show no detections above QL, and

2.6.1 - 4/7/03

for the few detections that were reported, all were between the DL and QL and were reported as estimated or otherwise qualified. Please let us know if you would like us to resubmit that information to you.

If you have any questions regarding the information provided with this letter, please contact the undersigned.

Sincerely,

ARCADIS G&M, Inc.

Subject:
Dioxin Data Validation Samples Collected January 22, 2003, at Kingsford, Michigan

ARCADIS Geraghty & Miller Project No.:
WI000975.0021

This report summarizes the review and evaluation of the January 22, 2003 samples WWTP EFF and PHII EFF collected in Kingsford, Michigan. Samples were submitted to Severn Trent Laboratories (STL), Inc., in Knoxville, Tennessee for the analysis of Polychlorinated Dibenzodioxins (PCDDs) and Polychlorinated Dibenzofurans (PCDFs) using United States Environmental Protection Agency (USEPA) Method 1613 Revision B (USEPA Method 1613B) (October 1994). This method uses high-resolution gas chromatography/high-resolution mass spectrometry (HRGC/HRMS). Samples collected on January 22, 2003 were received by STL on January 24, 2003, and were assigned the STL project number H3A300238.

Samples WWTP EFF and PHII EFF were collected on January 22, 2003. Sample WWTP EFF was a composite of samples collected from three different times. Both the WWTP and PHII samples had a second portion filtered and analyzed. A total of four samples were analyzed. All samples were extracted February 3, 2003 and analyzed on February 11, 2003.

The evaluation of data quality was performed using the guidance documents entitled: "*Data Validation Standard Operating Procedures for Chlorinated Dioxin/Furan Analysis by High-Resolution Gas Chromatography/High-Resolution Mass Spectrometry, USEPA Region IV, Revision 3.0, dated May 2002*," and "*USEPA Analytical Operations/Data Quality Center (AOC) National Functional Guidelines for Chlorinated Dioxin/Furan Data Review dated August 2002*," the method specified criteria from USEPA Method 1613B, and professional judgment.

A detailed evaluation of the associated samples collected January 22, 2003 is presented in the following sections.

1.0 System performance Quality control Review

USEPA Method 1613B requires the use of HRGC/HRMS to detect and quantitate PCDD/PCDF. The high-resolution capillary column DB-5 was used for all analyses. Analytical results were reported to the estimated detection limit (EDL).

1.1 System Performance Check

Each instrument used for USEPA Method 1613B analysis was tuned using calibrant perfluorokerosene (PFK) for mass calibration and mass spectrometer resolution greater than or equal to 10,000, selective ion monitoring (SIM) scan descriptor switching times, and GC resolution. A system performance check was provided for each 12 hour analysis period, and for each instrument used during analysis. HRGC/HRMS instrument MAT95S was used to analyze the field samples and associated batch QC.

1.2 Initial Calibrations

Initial calibrations were reviewed for each of the instruments used for STL Report H3A300238. A five point initial calibration was performed by STL on the instrument. The following initial calibrations were reviewed: 9/12-13/02. The percent relative standard deviations (%RSDs), relative response factors (RRFs), signal to noise (S/N), retention time windows, and ion abundance ratios were reviewed against the method specified criteria. The associated initial calibrations were acceptable.

1.3 Continuing Calibrations

A continuing calibration (mid level standard) was analyzed prior to and following sample analysis. Less than the standard 12 hour analytical period was used. The continuing calibration was reviewed for each instrument RRFs, percent differences (%D), ion-abundance ratios, internal standard, and recovery compound, and was acceptable. The following continuing calibrations were reviewed in association with STL Report H3A300238: t 030211s2 associated with Method Blank, Laboratory Control Sample (LCS), PHII EFF (1/22/03)D, PHII EFF (1/22/03)T, WWTP EFF (1/22/03)T, and WWTP EFF (1/22/03)D. All continuing calibrations associated with STL Report H3A300238 were acceptable.

1.4 Method Blanks

Method blank (FG2X61AA) was extracted with the field samples in STL Report H3A300238. In accordance with the "Data Validation Standard Operating Procedures for Chlorinated Dioxin/Furan Analysis by High-Resolution Gas Chromatography/High-Resolution Mass Spectrometry, USEPA Region IV, Revision 3.0, dated May 2002," and "USEPA Analytical Operations/Data Quality Center (AOC) National Functional Guidelines for Chlorinated Dioxin/Furan Data Review dated August 2002," any target analyte detected in the associated method blank is evaluated against the associated field samples by multiplying the blank concentration by five times (action level). The associated field sample data values reported less than the Action Level are qualified as "U/Not Detected," inclusive of those values reported at the EDL or estimated maximum possible concentration (EMPC). All values detected in the method blank were less than the target

detection limit (Section 2.3 of this evaluation) and therefore, the method blank is determined to be acceptable. OCDD was detected in samples PHII EFF (1/22/03)T, PHII EFF (1/22/03)D, WWTP EFF (1/23/03)T, and WWTP EFF (1/23/03)D at concentrations (9.8, 7.0, 12, and 3.2 picograms per liter (pg/L), respectively) less than five times the concentration detected in the method blank (7.7 pg/L). OCDF was detected in the sample PHII EFF (1/22/03)D at a concentration (4.0 pg/L) that was less than five times the concentration in the method blank (5.7 pg/L). Therefore, all detected sample compounds for this report were assigned the value NOT Detected.

1.5 Rinsate Blanks

A rinsate blank, field QC sample was not collected in associated with samples reported in STL Report H3A300238.

1.6 Matrix Spikes/Matrix Spike Duplicates (MS/MSD)

Additional sample volume of the samples was not supplied for MS/MSD analyses. The analysis of MS/MSD on project related matrices not only provides precision and accuracy data but serves to determine if there are matrix interferences related to the method. Method accuracy was demonstrated though the analysis of an LCS.

1.7 Laboratory Control Sample(LCS)

One LCS (file FG2X61AC) was extracted in association with the field samples analyzed in STL Report H3A300238. All recoveries were reviewed against the in-house control limit criteria for LCS recovery. The LCS accuracy data was acceptable.

1.8 Duplicate Analyses

Additional sample volume of the samples was not supplied for duplicate sample analyses. The samples presented were duplicates with one being filtered and one not. But, because all compounds were considered non-detect, precision cannot be determined.

2.0 Sample Review

STL Report H3A300238 contained samples PHII EFF (1/22/03)D, PHII EFF (1/22/03)T, WWTP EFF (1/22/03)T, and WWTP EFF (1/22/03)D collected on January 22, 2003.

2.1 Holding Time

The chain-of-custody form was properly completed and signed and the groundwater sample was received in good condition and properly preserved at 4 degrees centigrade. The samples were extracted and analyzed within holding times.

2.2 Compound Identification

Sample results were reviewed against the method specific criteria for compound identification. Laboratory performance was acceptable.

All of the detected compounds were lower than five times the method blank detected levels. Therefore, all detected sample compounds were assigned the value NOT Detected.

2.3 Reporting

Target detection limits for USEPA Method 1613B are as follows for aqueous matrix:

$\leq$ 10 pg/L TCDD & TCDF
$\leq$ 50 pg/L Pent – Hepta CDD & CDF
$\leq$ 100 pg/L OCDD & OCDF

The laboratory reported EDL, presented on the analytical reports as the detection limit (DL), which represents the maximum possible concentration of a target analyte that could be present without being detected. The EDL was reported for non-detected values less than the method target detection limit and were calculated for each field sample.

2.4 Internal Standards

Fifteen internal standards are required by USEPA Method 1613B. All 15 labeled internals, surrogates, and alternate standards were reviewed against a control limit criteria of 40-130 percent recovery. STL has established in-house criteria. All labeled standards were reviewed for each of the associated field samples and found to be acceptable with the following exceptions:

WWTP EFF (1/22/03) – One internal standard was outside of the lower control limit criteria of 40-135 percent recovery. In accordance with the "*Data Validation Standard Operating Procedures for Chlorinated Dioxin/Furan Analysis by High-Resolution Gas Chromatography/High-Resolution Mass Spectrometry, USEPA Region IV, Revision 3.0, dated May 2002*," criteria, only detected values are qualified as "J/Estimated." Non detected values are qualified when the labeled standard recoveries are less than 10 percent. In this case, all of the labeled standards were less than 40 percent recovery but greater than 10 percent, and all of the associated sample results were non detect; therefore, no qualification was necessary.

3.0 Overall Data Assessment

The evaluation of data quality was performed using the following Guidance documents "Data Validation Standard Operating Procedures for Chlorinated Dioxin/Furan Analysis by High-Resolution Gas Chromatography/High-Resolution Mass Spectrometry, USEPA Region IV, Revision 3.0, dated May 2002," and "USEPA Analytical Operations/Data Quality Center (AOC) National Functional Guidelines for Chlorinated Dioxin/Furan Data Review dated August 2002," the method specified criteria from USEPA Method 1613B, and professional judgment. The field sample data for STL Report H3A300238 are presented in Attachment A. No data were rejected. OCDD was detected in samples PHII EFF (1/22/03)T, PHII EFF

(1/22/03)D, WWTP EFF (1/23/03)T, and WWTP EFF (1/23/03)D at concentrations (9.8, 7.0, 12, and 3.2 pg/L, respectively) less than five times the concentration detected in the method blank (7.7 pg/L). OCDF was detected in the sample PHII EFF (1/22/03)D at a concentration (4.0 pg/L) that was less than five times the concentration in the method blank (5.7 pg/L). Therefore, all detected sample compounds for this report were assigned the value NOT Detected. No other compounds were detected in either of these samples.

Subject:
Dioxin Data Validation Samples Collected February, 2003, at Kingsford, Michigan

ARCADIS Geraghty & Miller Project No.:
WI000975.0021

This report summarizes the review and evaluation of the February 13, 2003 samples PHII EFF collected in Kingsford, Michigan. Samples were submitted to Severn Trent Laboratories (STL), Inc., in Knoxville, Tennessee for the analysis of Polychlorinated Dibenzodioxins (PCDDs) and Polychlorinated Dibenzofurans (PCDFs) using United States Environmental Protection Agency (USEPA) Method 1613 Revision B (USEPA Method 1613B) (October 1994). This method uses high-resolution gas chromatography/high-resolution mass spectrometry (HRGC/HRMS). Samples collected on February 13, 2003 were received by STL on February 14, 2003, and were assigned the STL project number H3B140161.

The PHII EFF sample had a second portion filtered and analyzed. A total of two samples were analyzed. Both samples were extracted February 20, 2003 and analyzed on February 27, 2003.

The evaluation of data quality was performed using the guidance documents entitled: "*Data Validation Standard Operating Procedures for Chlorinated Dioxin/Furan Analysis by High-Resolution Gas Chromatography/High-Resolution Mass Spectrometry, USEPA Region IV, Revision 3.0, dated May 2002*," and "*USEPA Analytical Operations/Data Quality Center (AOC) National Functional Guidelines for Chlorinated Dioxin/Furan Data Review dated August 2002*," the method specified criteria from USEPA Method 1613B, and professional judgment.

A detailed evaluation of the associated samples collected February 13, 2003 is presented in the following sections.

1.0 System performance Quality control Review

USEPA Method 1613B requires the use of HRGC/HRMS to detect and quantitate PCDD/PCDF. The high-resolution capillary column DB-5 was used for all analyses. Analytical results were reported to the estimated detection limit (EDL).

1.1 System Performance Check

Each instrument used for USEPA Method 1613B analysis was tuned using calibrant perfluorokerosene (PFK) for mass calibration and mass spectrometer resolution greater than or equal to 10,000, selective ion monitoring (SIM) scan descriptor switching times, and GC resolution. A system performance check was provided for each 12 hour analysis period, and for each instrument used during analysis. HRGC/HRMS instrument MAT95S/M2A was used to analyze the field samples and associated batch QC.

1.2 Initial Calibrations

Initial calibrations were reviewed for the instrument used for STL Report H3B140161. A five point initial calibration was performed by STL on the instrument. The following initial calibrations were reviewed: 9/12-13/02. The percent relative standard deviations (%RSDs), relative response factors (RRFs), signal to noise (S/N), retention time windows, and ion abundance ratios were reviewed against the method specified criteria. The associated initial calibrations were acceptable.

1.3 Continuing Calibrations

A continuing calibration (mid level standard) was analyzed prior to and following sample analysis. Less than the standard 12 hour analytical period was used. The continuing calibration was reviewed for each instrument RRFs, percent differences (%D), ion-abundance ratios, internal standard, and recovery compound, and was acceptable. The following continuing calibrations were reviewed in association with STL Report H3B140161: t 030227s1 associated with Method Blank, Laboratory Control Sample (LCS), PHII EFF (2/13/03)D, and PHII EFF (2/13/03)T. All continuing calibrations associated with STL Report H3B140161 were acceptable.

1.4 Method Blanks

Method blank (FHX421AA) was extracted with the field samples in STL Report H3B140161. In accordance with the "Data Validation Standard Operating Procedures for Chlorinated Dioxin/Furan Analysis by High-Resolution Gas Chromatography/High-Resolution Mass Spectrometry, USEPA Region IV, Revision 3.0, dated May 2002," and "USEPA Analytical Operations/Data Quality Center (AOC) National Functional Guidelines for Chlorinated Dioxin/Furan Data Review dated August 2002," any target analyte detected in the associated method blank is evaluated against the associated field samples by multiplying the blank concentration by five times (action level). The associated field sample data values reported less than the Action Level are qualified as "U/Not Detected," inclusive of those values reported at the EDL or estimated maximum possible concentration (EMPC). All values detected in the method blank were less than the target

detection limit (Section 2.3 of this evaluation) and therefore, the method blank is determined to be acceptable. OCDD was detected in samples PHII EFF (2/13/03)T and PHII EFF (2/13/03)D at concentrations (5.2 and 3.5 picograms per liter (pg/L), respectively) less than five times the concentration detected in the method blank (6.1 pg/L). Therefore, all detected sample compounds for this report were assigned the value NOT Detected.

1.5 Rinsate Blanks

A rinsate blank, field QC sample was not collected in associated with samples reported in STL Report H3B140161.

1.6 Matrix Spikes/Matrix Spike Duplicates (MS/MSD)

Additional sample volume of the samples was not supplied for MS/MSD analyses. The analysis of MS/MSD on project related matrices not only provides precision and accuracy data but serves to determine if there are matrix interferences related to the method. Method accuracy was demonstrated though the analysis of an LCS.

1.7 Laboratory Control Sample(LCS)

One LCS (file FHX421AC) was extracted in association with the field samples analyzed in STL Report H3B140161. All recoveries were reviewed against the in-house control limit criteria for LCS recovery. The LCS accuracy data was acceptable.

1.8 Duplicate Analyses

Additional sample volume of the samples was not supplied for duplicate sample analyses. The samples presented were duplicates with one being filtered and one not. But, because all compounds were considered non-detect, precision cannot be determined.

2.0 Sample Review

STL Report H3B140161 contained samples PHII EFF (2/13/03)D, and PHII EFF (2/13/03)T, collected on February 13, 2003.

2.1 Holding Time

The chain-of-custody form was properly completed and signed and the groundwater sample was received in good condition and properly preserved at 4 degrees centigrade. The samples were extracted and analyzed within holding times.

2.2 Compound Identification

Sample results were reviewed against the method specific criteria for compound identification. Laboratory performance was acceptable.

All of the detected compounds were lower than five times the method blank detected levels. Therefore, all detected sample compounds were assigned the value NOT Detected.

2.3 Reporting

Target detection limits for USEPA Method 1613B are as follows for aqueous matrix:

≤ 10 pg/L TCDD & TCDF
≤ 50 pg/L Pent – Hepta CDD & CDF
≤ 100 pg/L OCDD & OCDF

The laboratory reported EDL, presented on the analytical reports as the detection limit (DL), which represents the maximum possible concentration of a target analyte that could be present without being detected. The EDL was reported for non-detected values less than the method target detection limit and were calculated for each field sample.

2.4 Internal Standards

Fifteen internal standards are required by USEPA Method 1613B. All 15 labeled internals, surrogates, and alternate standards were reviewed against a control limit criteria of 40-130 percent recovery. STL has established in-house criteria. All labeled standards were reviewed for each of the associated field samples and found to be acceptable with the following exceptions:

None

3.0 Overall Data Assessment

The evaluation of data quality was performed using the following Guidance documents "Data Validation Standard Operating Procedures for Chlorinated Dioxin/Furan Analysis by High-Resolution Gas Chromatography/High-Resolution Mass Spectrometry, USEPA Region IV, Revision 3.0, dated May 2002," and "USEPA Analytical Operations/Data Quality Center (AOC) National Functional Guidelines for Chlorinated Dioxin/Furan Data Review dated August 2002," the method specified criteria from USEPA Method 1613B, and professional judgment. The field sample data for STL Report H3B140161 are presented in Attachment A. No data were rejected. OCDD was detected in samples PHII EFF (2/13/03)T and PHII EFF (2/13/03)D at concentrations (5.2 and 3.5 pg/L, respectively) less than five times the concentration detected in the method blank (6.1 pg/L). Therefore, all detected sample compounds for this report were assigned the value NOT Detected. No other compounds were detected in either of these samples.

Dioxin Data Validation Samples Collected February, 2003, at Kingsford, Michigan

ARCADIS Geraghty & Miller Project No.:
WI000975.0021

This report summarizes the review and evaluation of the February 13, 2003 samples WWTP EFF collected in Kingsford, Michigan. Samples were submitted to Severn Trent Laboratories (STL), Inc., in Knoxville, Tennessee for the analysis of Polychlorinated Dibenzodioxins (PCDDs) and Polychlorinated Dibenzofurans (PCDFs) using United States Environmental Protection Agency (USEPA) Method 1613 Revision B (USEPA Method 1613B) (October 1994). This method uses high-resolution gas chromatography/high-resolution mass spectrometry (HRGC/HRMS). Samples collected on February 13, 2003 were received by STL on February 15, 2003, and were assigned the STL project number H3B170102.

Sample WWTP EFF was a composite of samples collected from three different times. The WWTP sample had a second portion filtered and analyzed. A total of two samples were analyzed. Both samples were extracted February 20, 2003 and analyzed on February 27, 2003.

The evaluation of data quality was performed using the guidance documents entitled: "*Data Validation Standard Operating Procedures for Chlorinated Dioxin/Furan Analysis by High-Resolution Gas Chromatography/High-Resolution Mass Spectrometry, USEPA Region IV, Revision 3.0, dated May 2002*," and "*USEPA Analytical Operations/Data Quality Center (AOC) National Functional Guidelines for Chlorinated Dioxin/Furan Data Review dated August 2002*," the method specified criteria from USEPA Method 1613B, and professional judgment.

A detailed evaluation of the associated samples collected February 13, 2003 is presented in the following sections.

1.0 System performance Quality control Review

USEPA Method 1613B requires the use of HRGC/HRMS to detect and quantitate PCDD/PCDF. The high-resolution capillary column DB-5 was used for all analyses. Analytical results were reported to the estimated detection limit (EDL).

1.1 System Performance Check

Each instrument used for USEPA Method 1613B analysis was tuned using calibrant perfluorokerosene (PFK) for mass calibration and mass spectrometer resolution greater than or equal to 10,000, selective ion monitoring (SIM) scan descriptor switching times, and GC resolution. A system performance check was provided for each 12 hour analysis period, and for each instrument used during analysis. HRGC/HRMS instrument MAT95S/M2A was used to analyze the field samples and associated batch QC.

1.2 Initial Calibrations

Initial calibrations were reviewed for the instrument used for STL Report H3B170102. A five point initial calibration was performed by STL on the instrument. The following initial calibrations were reviewed: 9/12-13/02. The percent relative standard deviations (%RSDs), relative response factors (RRFs), signal to noise (S/N), retention time windows, and ion abundance ratios were reviewed against the method specified criteria. The associated initial calibrations were acceptable.

1.3 Continuing Calibrations

A continuing calibration (mid level standard) was analyzed prior to and following sample analysis. Less than the standard 12 hour analytical period was used. The continuing calibration was reviewed for each instrument RRFs, percent differences (%D), ion-abundance ratios, internal standard, and recovery compound, and was acceptable. The following continuing calibrations were reviewed in association with STL Report H3B170102: t 030227s1 associated with Method Blank, Laboratory Control Sample (LCS), WWTP EFF (2/13/03)D, and WWTP EFF (2/13/03)T. All continuing calibrations associated with STL Report H3B170102 were acceptable.

1.4 Method Blanks

Method blank (FHX421AA) was extracted with the field samples in STL Report H3B170102. In accordance with the *"Data Validation Standard Operating Procedures for Chlorinated Dioxin/Furan Analysis by High-Resolution Gas Chromatography/High-Resolution Mass Spectrometry, USEPA Region IV, Revision 3.0, dated May 2002,"* and *"USEPA Analytical Operations/Data Quality Center (AOC) National Functional Guidelines for Chlorinated Dioxin/Furan Data Review dated August 2002,"* any target analyte detected in the associated method blank is evaluated against the associated field samples by multiplying the blank concentration by five times (action level). The associated field sample data values reported less than the Action Level are qualified as "U/Not Detected," inclusive of those values reported at the EDL or estimated maximum possible concentration (EMPC). All values detected in the method blank were less than the target detection limit

(Section 2.3 of this evaluation) and therefore, the method blank is determined to be acceptable. OCDD was detected in sample WWTP EFF (2/13/03)T at a concentration (7.1 picograms per liter (pg/L)) that was less than five times the concentration detected in the method blank (6.1 pg/L). Therefore, all detected sample compounds for this report were assigned the value NOT Detected.

1.5 Rinsate Blanks

A rinsate blank, field QC sample was not collected in associated with samples reported in STL Report H3B170102.

1.6 Matrix Spikes/Matrix Spike Duplicates (MS/MSD)

Additional sample volume of the samples was not supplied for MS/MSD analyses. The analysis of MS/MSD on project related matrices not only provides precision and accuracy data but serves to determine if there are matrix interferences related to the method. Method accuracy was demonstrated though the analysis of an LCS.

1.7 Laboratory Control Sample(LCS)

One LCS (file FHX421AC) was extracted in association with the field samples analyzed in STL Report H3B170102. All recoveries were reviewed against the in-house control limit criteria for LCS recovery. The LCS accuracy data was acceptable.

1.8 Duplicate Analyses

Additional sample volume of the samples was not supplied for duplicate sample analyses. The samples presented were duplicates with one being filtered and one not. But, because all compounds were considered non-detect, precision cannot be determined.

2.0 Sample Review

STL Report H3B170102 contained composited samples WWTP EFF (2/13/03)D, and WWTP EFF (2/13/03)T, collected on February 13, 2003.

2.1 Holding Time

The chain-of-custody form was properly completed and signed and the groundwater sample was received in good condition and properly preserved at 4 degrees centigrade. The samples were extracted and analyzed within holding times.

2.2 Compound Identification

Sample results were reviewed against the method specific criteria for compound identification. Laboratory performance was acceptable.

All of the detected compounds were lower than five times the method blank detected levels. Therefore, all detected sample compounds were assigned the value NOT Detected.

2.3 Reporting

Target detection limits for USEPA Method 1613B are as follows for aqueous matrix:

≤ 10 pg/L TCDD & TCDF
≤ 50 pg/L Pent – Hepta CDD & CDF
≤ 100 pg/L OCDD & OCDF

The laboratory reported EDL, presented on the analytical reports as the detection limit (DL), which represents the maximum possible concentration of a target analyte that could be present without being detected. The EDL was reported for non-detected values less than the method target detection limit and were calculated for each field sample.

2.4 Internal Standards

Fifteen internal standards are required by USEPA Method 1613B. All 15 labeled internals, surrogates, and alternate standards were reviewed against a control limit criteria of 40-130 percent recovery. STL has established in-house criteria. All labeled standards were reviewed for each of the associated field samples and found to be acceptable with the following exceptions:

None

3.0 Overall Data Assessment

The evaluation of data quality was performed using the following Guidance documents "Data Validation Standard Operating Procedures for Chlorinated Dioxin/Furan Analysis by High-Resolution Gas Chromatography/High-Resolution Mass Spectrometry, USEPA Region IV, Revision 3.0, dated May 2002," and "USEPA Analytical Operations/Data Quality Center (AOC) National Functional Guidelines for Chlorinated Dioxin/Furan Data Review dated August 2002," the method specified criteria from USEPA Method 1613B, and professional judgment. The field sample data for STL Report H3B170102 are presented in Attachment A. No data were rejected. OCDD was detected in sample WWTP EFF (2/13/03)T at a concentration (7.1 pg/L) that was less than five times the concentration detected in the method blank (6.1 pg/L). Therefore, all detected sample compounds for this report were assigned the value NOT Detected. No other compounds were detected in either of these samples.

(ND) Detected result was qualified as "not detected" due to associated blank contamination; contribution to the TEC is zero.

BEF Bioaccumulation equivalency factor [MDEQ, Rule 323.1209(4)(ii)].

DL Detection limit.

NA Information is not available.

ND Congener was not detected; contribution to the TEC is zero.

ppq Parts per quadrillion (picograms per liter).

QL Congener quantification level.

TEC Toxicity equivalence concentration of 2,3,7,8-TCDD.

TEF Toxicity equivalency factor [MDEQ, Rule 323.1209(4)(ii)].

ppq Parts per quadrillion (picograms per liter).

* TEC (ppq) = Detected result (ppq) × BEF × TEF

Data Qualifiers:

B – Compound was detected in the associated QC method blank sample.

E – Estimated maximum possible concentration.

J – Concentration is qualified as estimated.

K – Concentration exceeds the calibration curve; qualified as estimated.

U – Result was qualified as "not detected" during data validation.

Q – Estimated maximum possible concentration.

Dear Mr. Casey:

In response to a request from the Michigan Department of Environmental Quality (MDEQ), and in accordance with a proposal dated January 10, 2003, which was approved by the MDEQ, monthly monitoring of the Iron Mountain/Kingsford (IMK) Wastewater Treatment Plant (WWTP) effluent for polychlorinated dibenzo-p-dioxins (dioxins) and polychlorinated dibenzofurans (furans) was performed in January, February, and March 2003. ARCADIS, on behalf of the IMK Joint Sewage Board, has prepared this letter to transmit the results of that monitoring effort.

WWTP Effluent Dioxin Concentrations

The January 22, February 13, and March 4, 2003 dioxin and furan monitoring results for the IMK WWTP effluent are summarized in Tables 1 through 3. Samples of the effluent following dechlorination were collected 3 times per day at approximately 7 am, 3 pm, and 11 pm to make a composite sample that was representative of flow throughout the day. The individual samples were shipped on ice to Severn Trent Laboratories (STL) in Knoxville, Tennessee. Equal volumes of each sample were combined at the laboratory to make a single composite sample that was analyzed for dioxins and furans using United States Environmental Protection Agency Method 1613. The compositing was performed in the laboratory to minimize the potential for field contamination.

The results presented in Table 2 and Table 3 show that there are no detectable concentrations of dioxins or furans present in the effluent from the IMK WWTP. Table 2 presents the results for total dioxins and furans while Table 3 presents the results for dissolved dioxins and furans. The detection limits achieved by STL were lower than the minimum practical quantitation levels required by the MDEQ. The data presented in Tables 2 and 3 was validated by ARCADIS and the validation reports are provided in Attachment A. The laboratory reports generated by STL are being transmitted to the MDEQ under separate cover by ARCADIS.

Closing Remarks

The IMK Joint Sewage Board and ARCADIS appreciate MDEQ's support and understanding as we work cooperatively through this issue. If you have any questions regarding this submittal, please contact me at (813) 961-1921 or you may also contact Gary Lessard at (906) 774-2255.

Sincerely,

Subject:
Dioxin Data Validation Samples Collected March, 2003, at Kingsford, Michigan

ARCADIS Geraghty & Miller Project No.:
WI000975.0021

This report summarizes the review and evaluation of the March 4, 2003 samples WWTP EFF collected in Kingsford, Michigan. Samples were submitted to Severn Trent Laboratories (STL), Inc., in Knoxville, Tennessee for the analysis of Polychlorinated Dibenzodioxins (PCDDs) and Polychlorinated Dibenzofurans (PCDFs) using United States Environmental Protection Agency (USEPA) Method 1613 Revision B (USEPA Method 1613B) (October 1994). This method uses high-resolution gas chromatography/high-resolution mass spectrometry (HRGC/HRMS). Samples collected on March 4, 2003 were received by STL on March 6, 2003, and were assigned the STL project number H3C060154.

Sample WWTP EFF was a composite of samples collected from three different times. The WWTP sample had a second portion filtered and analyzed. A total of two samples were analyzed. Both samples were extracted March 7, 2003 and analyzed on March 26, 2003.

The evaluation of data quality was performed using the guidance documents entitled: "*Data Validation Standard Operating Procedures for Chlorinated Dioxin/Furan Analysis by High-Resolution Gas Chromatography/High-Resolution Mass Spectrometry, USEPA Region IV, Revision 3.0, dated May 2002*," and "*USEPA Analytical Operations/Data Quality Center (AOC) National Functional Guidelines for Chlorinated Dioxin/Furan Data Review dated August 2002*," the method specified criteria from USEPA Method 1613B, and professional judgment.

A detailed evaluation of the associated samples collected March 4, 2003 is presented in the following sections.

1.0 System performance Quality control Review

USEPA Method 1613B requires the use of HRGC/HRMS to detect and quantitate PCDD/PCDF. The high-resolution capillary column DB-5 was used for all analyses. Analytical results were reported to the estimated detection limit (EDL).

1.1 System Performance Check

Each instrument used for USEPA Method 1613B analysis was tuned using calibrant perfluorokerosene (PFK) for mass calibration and mass spectrometer resolution greater than or equal to 10,000, selective ion monitoring (SIM) scan descriptor switching times, and GC resolution. A system performance check was provided for each 12 hour analysis period, and for each instrument used during analysis. HRGC/HRMS instrument MAT95S/M2A was used to analyze the field samples and associated batch QC.

1.2 Initial Calibrations

Initial calibrations were reviewed for the instrument used for STL Report H3C060154. A five point initial calibration was performed by STL on the instrument. The following initial calibrations were reviewed: 9/12-13/02. The percent relative standard deviations (%RSDs), relative response factors (RRFs), signal to noise (S/N), retention time windows, and ion abundance ratios were reviewed against the method specified criteria. The associated initial calibrations were acceptable.

1.3 Continuing Calibrations

A continuing calibration (mid level standard) was analyzed prior to and following sample analysis. Less than the standard 12 hour analytical period was used. The continuing calibration was reviewed for each instrument RRFs, percent differences (%D), ion-abundance ratios, internal standard, and recovery compound, and was acceptable. The following continuing calibrations were reviewed in association with STL Report H3C060154: t 030325s4 associated with Method Blank, Laboratory Control Sample (LCS), WWTP EFF (3/04/03)D, and WWTP EFF (3/04/03)T. All continuing calibrations associated with STL Report H3C060154 were acceptable.

1.4 Method Blanks

Method blank (FJQ9A1AA) was extracted with the field samples in STL Report H3C060154. In accordance with the *"Data Validation Standard Operating Procedures for Chlorinated Dioxin/Furan Analysis by High-Resolution Gas Chromatography/High-Resolution Mass Spectrometry, USEPA Region IV, Revision 3.0, dated May 2002,"* and *"USEPA Analytical Operations/Data Quality Center (AOC) National Functional Guidelines for Chlorinated Dioxin/Furan Data Review dated August 2002,"* any target analyte detected in the associated method blank is evaluated against the associated field samples by multiplying the blank concentration by five times (action level). The associated field sample data values reported less than the Action Level are qualified as "U/Not Detected," inclusive of those values reported at the EDL or estimated maximum possible concentration (EMPC). All values detected in the method blank were less than the target detection limit

(Section 2.3 of this evaluation) and therefore, the method blank is determined to be acceptable. OCDD was detected in sample WWTP EFF (3/04/03)T at a concentration (14 picograms per liter (pg/L)) that was less than five times the concentration detected in the method blank (9.5 pg/L). OCDF was detected in sample WWTP EFF (3/04/03)T at a concentration (6.8 pg/L) that was less than five times the concentration detected in the method blank (6.8 pg/L). Therefore, all detected sample compounds for this report were assigned the value NOT Detected.

1.5 Rinsate Blanks

A rinsate blank, field QC sample was not collected in associated with samples reported in STL Report H3C060154.

1.6 Matrix Spikes/Matrix Spike Duplicates (MS/MSD)

Additional sample volume of the samples was not supplied for MS/MSD analyses. Method accuracy was demonstrated though the analysis of a LCS.

1.7 Laboratory Control Sample (LCS)

One LCS (file FJQ9A1AC) was extracted in association with the field samples analyzed in STL Report H3C060154. All recoveries were reviewed against the in-house control limit criteria for LCS recovery. The LCS accuracy data was acceptable.

1.8 Duplicate Analyses

Additional sample volume of the samples was not supplied for duplicate sample analyses. The samples presented were duplicates with one being filtered and one not. But, because all compounds were considered non-detect, precision cannot be determined.

2.0 Sample Review

STL Report H3C060154 contained composited samples WWTP EFF (3/04/03)D, and WWTP EFF (3/04/03)T, collected on March 4, 2003.

2.1 Holding Time

The chain-of-custody form was properly completed and signed and the groundwater sample was received in good condition and properly preserved at or below 4 degrees centigrade. The samples were extracted and analyzed within holding times.

2.2 Compound Identification

Sample results were reviewed against the method specific criteria for compound identification. Laboratory performance was acceptable.

All of the detected compounds were lower than five times the method blank detected levels. Therefore, all detected sample compounds were assigned the value NOT Detected.

2.3 Reporting

Target detection limits for USEPA Method 1613B are as follows for aqueous matrix:

≤ 10 pg/L TCDD & TCDF
≤ 50 pg/L Pent – Hepta CDD & CDF
≤ 100 pg/L OCDD & OCDF

The laboratory reported EDL, presented on the analytical reports as the detection limit (DL), which represents the maximum possible concentration of a target analyte that could be present without being detected. The EDL was reported for non-detected values less than the method target detection limit and were calculated for each field sample.

2.4 Internal Standards

Fifteen internal standards are required by USEPA Method 1613B. All 15 labeled internals, surrogates, and alternate standards were reviewed against a control limit criteria of 40-130 percent recovery. STL has established in-house criteria. All labeled standards were reviewed for each of the associated field samples and found to be acceptable with the following exceptions:

None

3.0 Overall Data Assessment

The evaluation of data quality was performed using the following Guidance documents "Data Validation Standard Operating Procedures for Chlorinated Dioxin/Furan Analysis by High-Resolution Gas Chromatography/High-Resolution Mass Spectrometry, USEPA Region IV, Revision 3.0, dated May 2002," and "USEPA Analytical Operations/Data Quality Center (AOC) National Functional Guidelines for Chlorinated Dioxin/Furan Data Review dated August 2002," the method specified criteria from USEPA Method 1613B, and professional judgment. The field sample data for STL Report H3C060154 are presented in Attachment A. No data were rejected. OCDD was detected in sample WWTP EFF (3/04/03)T at a concentration (14 pg/L) that was less than five times the concentration detected in the method blank (9.5 pg/L). OCDF was detected in sample WWTP EFF (3/04/03)T at a concentration (6.8 pg/L) that was less than five times the concentration detected in the method blank (6.8 pg/L). Therefore, all detected sample compounds for this report were assigned the value NOT Detected. No other compounds were detected in either of these samples.

Subject:
Dioxin Data Validation Samples Collected January 22, 2003, at Kingsford, Michigan

ARCADIS Geraghty & Miller Project No.:
WI000975.0021

This report summarizes the review and evaluation of the January 22, 2003 samples WWTP EFF and PHII EFF collected in Kingsford, Michigan. Samples were submitted to Severn Trent Laboratories (STL), Inc., in Knoxville, Tennessee for the analysis of Polychlorinated Dibenzodioxins (PCDDs) and Polychlorinated Dibenzofurans (PCDFs) using United States Environmental Protection Agency (USEPA) Method 1613 Revision B (USEPA Method 1613B) (October 1994). This method uses high-resolution gas chromatography/high-resolution mass spectrometry (HRGC/HRMS). Samples collected on January 22, 2003 were received by STL on January 24, 2003, and were assigned the STL project number H3A300238.

Samples WWTP EFF and PHII EFF were collected on January 22, 2003. Sample WWTP EFF was a composite of samples collected from three different times. Both the WWTP and PHII samples had a second portion filtered and analyzed. A total of four samples were analyzed. All samples were extracted February 3, 2003 and analyzed on February 11, 2003.

The evaluation of data quality was performed using the guidance documents entitled: "*Data Validation Standard Operating Procedures for Chlorinated Dioxin/Furan Analysis by High-Resolution Gas Chromatography/High-Resolution Mass Spectrometry, USEPA Region IV, Revision 3.0, dated May 2002*," and "*USEPA Analytical Operations/Data Quality Center (AOC) National Functional Guidelines for Chlorinated Dioxin/Furan Data Review dated August 2002*," the method specified criteria from USEPA Method 1613B, and professional judgment.

A detailed evaluation of the associated samples collected January 22, 2003 is presented in the following sections.

1.0 System performance Quality control Review

USEPA Method 1613B requires the use of HRGC/HRMS to detect and quantitate PCDD/PCDF. The high-resolution capillary column DB-5 was used for all analyses. Analytical results were reported to the estimated detection limit (EDL).

1.1 System Performance Check

Each instrument used for USEPA Method 1613B analysis was tuned using calibrant perfluorokerosene (PFK) for mass calibration and mass spectrometer resolution greater than or equal to 10,000, selective ion monitoring (SIM) scan descriptor switching times, and GC resolution. A system performance check was provided for each 12 hour analysis period, and for each instrument used during analysis. HRGC/HRMS instrument MAT95S was used to analyze the field samples and associated batch QC.

1.2 Initial Calibrations

Initial calibrations were reviewed for each of the instruments used for STL Report H3A300238. A five point initial calibration was performed by STL on the instrument. The following initial calibrations were reviewed: 9/12-13/02. The percent relative standard deviations (%RSDs), relative response factors (RRFs), signal to noise (S/N), retention time windows, and ion abundance ratios were reviewed against the method specified criteria. The associated initial calibrations were acceptable.

1.3 Continuing Calibrations

A continuing calibration (mid level standard) was analyzed prior to and following sample analysis. Less than the standard 12 hour analytical period was used. The continuing calibration was reviewed for each instrument RRFs, percent differences (%D), ion-abundance ratios, internal standard, and recovery compound, and was acceptable. The following continuing calibrations were reviewed in association with STL Report H3A300238: t 030211s2 associated with Method Blank, Laboratory Control Sample (LCS), PHII EFF (1/22/03)D, PHII EFF (1/22/03)T, WWTP EFF (1/22/03)T, and WWTP EFF (1/22/03)D. All continuing calibrations associated with STL Report H3A300238 were acceptable.

1.4 Method Blanks

Method blank (FG2X61AA) was extracted with the field samples in STL Report H3A300238. In accordance with the "Data Validation Standard Operating Procedures for Chlorinated Dioxin/Furan Analysis by High-Resolution Gas Chromatography/High-Resolution Mass Spectrometry, USEPA Region IV, Revision 3.0, dated May 2002," and "USEPA Analytical Operations/Data Quality Center (AOC) National Functional Guidelines for Chlorinated Dioxin/Furan Data Review dated August 2002," any target analyte detected in the associated method blank is evaluated against the associated field samples by multiplying the blank concentration by five times (action level). The associated field sample data values reported less than the Action Level are qualified as "U/Not Detected," inclusive of those values reported at the EDL or estimated maximum possible concentration (EMPC). All values detected in the method blank were less than the target

Date:
March 18, 2003

Subject:
Dioxin Data Validation Samples Collected February, 2003, at Kingsford, Michigan

ARCADIS Geraghty & Miller Project No.:
WI000975.0021

This report summarizes the review and evaluation of the February 13, 2003 samples WWTP EFF collected in Kingsford, Michigan. Samples were submitted to Severn Trent Laboratories (STL), Inc., in Knoxville, Tennessee for the analysis of Polychlorinated Dibenzodioxins (PCDDs) and Polychlorinated Dibenzofurans (PCDFs) using United States Environmental Protection Agency (USEPA) Method 1613 Revision B (USEPA Method 1613B) (October 1994). This method uses high-resolution gas chromatography/high-resolution mass spectrometry (HRGC/HRMS). Samples collected on February 13, 2003 were received by STL on February 15, 2003, and were assigned the STL project number H3B170102.

Sample WWTP EFF was a composite of samples collected from three different times. The WWTP sample had a second portion filtered and analyzed. A total of two samples were analyzed. Both samples were extracted February 20, 2003 and analyzed on February 27, 2003.

The evaluation of data quality was performed using the guidance documents entitled: "*Data Validation Standard Operating Procedures for Chlorinated Dioxin/Furan Analysis by High-Resolution Gas Chromatography/High-Resolution Mass Spectrometry, USEPA Region IV, Revision 3.0, dated May 2002*," and "*USEPA Analytical Operations/Data Quality Center (AOC) National Functional Guidelines for Chlorinated Dioxin/Furan Data Review dated August 2002*," the method specified criteria from USEPA Method 1613B, and professional judgment.

A detailed evaluation of the associated samples collected February 13, 2003 is presented in the following sections.

1.0 System performance Quality control Review

USEPA Method 1613B requires the use of HRGC/HRMS to detect and quantitate PCDD/PCDF. The high-resolution capillary column DB-5 was used for all analyses. Analytical results were reported to the estimated detection limit (EDL).

1.1 System Performance Check

Each instrument used for USEPA Method 1613B analysis was tuned using calibrant perfluorokerosene (PFK) for mass calibration and mass spectrometer resolution greater than or equal to 10,000, selective ion monitoring (SIM) scan descriptor switching times, and GC resolution. A system performance check was provided for each 12 hour analysis period, and for each instrument used during analysis. HRGC/HRMS instrument MAT95S/M2A was used to analyze the field samples and associated batch QC.

1.2 Initial Calibrations

Initial calibrations were reviewed for the instrument used for STL Report H3B170102. A five point initial calibration was performed by STL on the instrument. The following initial calibrations were reviewed: 9/12-13/02. The percent relative standard deviations (%RSDs), relative response factors (RRFs), signal to noise (S/N), retention time windows, and ion abundance ratios were reviewed against the method specified criteria. The associated initial calibrations were acceptable.

1.3 Continuing Calibrations

A continuing calibration (mid level standard) was analyzed prior to and following sample analysis. Less than the standard 12 hour analytical period was used. The continuing calibration was reviewed for each instrument RRFs, percent differences (%D), ion-abundance ratios, internal standard, and recovery compound, and was acceptable. The following continuing calibrations were reviewed in association with STL Report H3B170102: t 030227s1 associated with Method Blank, Laboratory Control Sample (LCS), WWTP EFF (2/13/03)D, and WWTP EFF (2/13/03)T. All continuing calibrations associated with STL Report H3B170102 were acceptable.

1.4 Method Blanks

Method blank (FHX421AA) was extracted with the field samples in STL Report H3B170102. In accordance with the *"Data Validation Standard Operating Procedures for Chlorinated Dioxin/Furan Analysis by High-Resolution Gas Chromatography/High-Resolution Mass Spectrometry, USEPA Region IV, Revision 3.0, dated May 2002,"* and *"USEPA Analytical Operations/Data Quality Center (AOC) National Functional Guidelines for Chlorinated Dioxin/Furan Data Review dated August 2002,"* any target analyte detected in the associated method blank is evaluated against the associated field samples by multiplying the blank concentration by five times (action level). The associated field sample data values reported less than the Action Level are qualified as "U/Not Detected," inclusive of those values reported at the EDL or estimated maximum possible concentration (EMPC). All values detected in the method blank were less than the target detection limit

(Section 2.3 of this evaluation) and therefore, the method blank is determined to be acceptable. OCDD was detected in sample WWTP EFF (2/13/03)T at a concentration (7.1 picograms per liter (pg/L)) that was less than five times the concentration detected in the method blank (6.1 pg/L). Therefore, all detected sample compounds for this report were assigned the value NOT Detected.

1.5 Rinsate Blanks

A rinsate blank, field QC sample was not collected in associated with samples reported in STL Report H3B170102.

1.6 Matrix Spikes/Matrix Spike Duplicates (MS/MSD)

Additional sample volume of the samples was not supplied for MS/MSD analyses. Method accuracy was demonstrated though the analysis of a LCS.

1.7 Laboratory Control Sample (LCS)

One LCS (file FHX421AC) was extracted in association with the field samples analyzed in STL Report H3B170102. All recoveries were reviewed against the in-house control limit criteria for LCS recovery. The LCS accuracy data was acceptable.

1.8 Duplicate Analyses

Additional sample volume of the samples was not supplied for duplicate sample analyses. The samples presented were duplicates with one being filtered and one not. But, because all compounds were considered non-detect, precision cannot be determined.

2.0 Sample Review

STL Report H3B170102 contained composited samples WWTP EFF (2/13/03)D, and WWTP EFF (2/13/03)T, collected on February 13, 2003.

2.1 Holding Time

The chain-of-custody form was properly completed and signed and the groundwater sample was received in good condition and properly preserved at 4 degrees centigrade. The samples were extracted and analyzed within holding times.

2.2 Compound Identification

Sample results were reviewed against the method specific criteria for compound identification. Laboratory performance was acceptable.

All of the detected compounds were lower than five times the method blank detected levels. Therefore, all detected sample compounds were assigned the value NOT Detected.

2.3 Reporting

Target detection limits for USEPA Method 1613B are as follows for aqueous matrix:

≤ 10 pg/L TCDD & TCDF
≤ 50 pg/L Pent – Hepta CDD & CDF
≤ 100 pg/L OCDD & OCDF

The laboratory reported EDL, presented on the analytical reports as the detection limit (DL), which represents the maximum possible concentration of a target analyte that could be present without being detected. The EDL was reported for non-detected values less than the method target detection limit and were calculated for each field sample.

2.4 Internal Standards

Fifteen internal standards are required by USEPA Method 1613B. All 15 labeled internals, surrogates, and alternate standards were reviewed against a control limit criteria of 40-130 percent recovery. STL has established in-house criteria. All labeled standards were reviewed for each of the associated field samples and found to be acceptable with the following exceptions:

None

3.0 Overall Data Assessment

The evaluation of data quality was performed using the following Guidance documents "Data Validation Standard Operating Procedures for Chlorinated Dioxin/Furan Analysis by High-Resolution Gas Chromatography/High-Resolution Mass Spectrometry, USEPA Region IV, Revision 3.0, dated May 2002," and "USEPA Analytical Operations/Data Quality Center (AOC) National Functional Guidelines for Chlorinated Dioxin/Furan Data Review dated August 2002," the method specified criteria from USEPA Method 1613B, and professional judgment. The field sample data for STL Report H3B170102 are presented in Attachment A. No data were rejected. OCDD was detected in sample WWTP EFF (2/13/03)T at a concentration (7.1 pg/L) that was less than five times the concentration detected in the method blank (6.1 pg/L). Therefore, all detected sample compounds for this report were assigned the value NOT Detected. No other compounds were detected in either of these samples.

Dear Mr. Casey:

In response to a request from the Michigan Department of Environmental Quality (MDEQ), and in accordance with a proposal dated January 10, 2003, which was approved by the MDEQ, monthly monitoring of the Iron Mountain/Kingsford (IMK) Wastewater Treatment Plant (WWTP) effluent for polychlorinated dibenzo-p-dioxins (dioxins) and polychlorinated dibenzofurans (furans) was performed in January, February, and March 2003. While not required by the MDEQ, the IMK Joint Sewage Board requested that Ford Motor Company (Ford) and The Kingsford Products Company (KPC) have the Phase II groundwater pretreatment system effluent sampled and analyzed for dioxins and furans concurrently with the sampling that was performed at the WWTP. ARCADIS, on behalf of Ford and KPC, has prepared this letter to transmit the results of that monitoring effort.

Phase II Effluent Dioxin Concentrations

On January 22, February 13, and March 4, 2003, ARCADIS sampled the Phase II effluent and shipped the samples on ice to STL in Knoxville, Tennessee where they were analyzed for dioxins and furans using United States Environmental Protection Agency Method 1613B. Consistent with previous sampling methods approved by the MDEQ for the Phase II effluent, a single grab sample was collected. Composite sampling was determined to not be necessary since a consistent flowrate through the treatment system can be maintained.

During the months of January, February, and March while the sampling was being performed, the groundwater being treated by the Phase II pretreatment system consisted primarily of groundwater extracted from Extraction Wells GMEW-1, GMEW-2, and GMEW-3, which contribute low strength, medium strength, and high strength groundwater (as measured by biochemical oxygen demand), respectively to the pretreatment system. The contribution of flow from each of the extraction wells during the sampling events is provided in Table 1.

The January 22, February 13, and March 4, 2003 dioxin and furan monitoring results for the Phase II effluent are summarized in Tables 2 through 4. The results presented in Tables 3 and 4 show that there are no detectable concentrations of dioxins or furans present in the effluent from the Phase II pretreatment system. Table 3 presents the results for total dioxins and furans while Table 4 presents the results for dissolved dioxins and furans. The detection limits achieved by STL were lower than the minimum PQLs required by the MDEQ. The data presented in Tables 3 and 4 was validated by ARCADIS and the validation reports are provided in Attachment A. The laboratory reports generated by STL are being transmitted to the MDEQ under separate cover by ARCADIS.

These data are considered to more accurately represent the effluent from the Phase II pretreatment system than the data collected and reported in the March 29, 2002 submittal that were analyzed by Triangle Laboratories. This determination is based on the following facts:

- All detections in the March 29, 2002 submittal were between the detection level and the PQL and were estimated or otherwise qualified results.

- Dioxin and furan congeners that were detected by Triangle Laboratories varied from sample to sample and from influent to effluent.

- Nearly 1/4 (22.5 percent) of the dioxin and furan congeners identified in the Phase II effluent samples that were reported in the March 29, 2002 submittal were qualified as non-detect due to the congener also being detected in the associated quality control method blank. Comparatively, less than 6 percent of the Phase II effluent samples collected in 2003 (analyzed by STL) were qualified as non-detect due to method blank contamination. This suggests there was a significantly higher level of laboratory contamination affecting sample accuracy in the 2002 data, particularly when congener levels are less than the PQL.

- The data generated by STL did not have the problems associated with the Triangle Laboratories data, and appears to be more accurate and representative of actual conditions.

Closing Remarks

Ford, KPC, and ARCADIS appreciate MDEQ's support and understanding as we work cooperatively through this issue. If you have any questions regarding this submittal, please contact me at (813) 961-1921.

Sincerely,

ARCADIS G&M, Inc.

Subject:
Dioxin Data Validation Samples Collected February, 2003, at Kingsford, Michigan

ARCADIS Geraghty & Miller Project No.:
WI000975.0021

This report summarizes the review and evaluation of the February 13, 2003 samples PHII EFF collected in Kingsford, Michigan. Samples were submitted to Severn Trent Laboratories (STL), Inc., in Knoxville, Tennessee for the analysis of Polychlorinated Dibenzodioxins (PCDDs) and Polychlorinated Dibenzofurans (PCDFs) using United States Environmental Protection Agency (USEPA) Method 1613 Revision B (USEPA Method 1613B) (October 1994). This method uses high-resolution gas chromatography/high-resolution mass spectrometry (HRGC/HRMS). Samples collected on February 13, 2003 were received by STL on February 14, 2003, and were assigned the STL project number H3B140161.

The PHII EFF sample had a second portion filtered and analyzed. A total of two samples were analyzed. Both samples were extracted February 20, 2003 and analyzed on February 27, 2003.

The evaluation of data quality was performed using the guidance documents entitled: "*Data Validation Standard Operating Procedures for Chlorinated Dioxin/Furan Analysis by High-Resolution Gas Chromatography/High-Resolution Mass Spectrometry, USEPA Region IV, Revision 3.0, dated May 2002*," and "*USEPA Analytical Operations/Data Quality Center (AOC) National Functional Guidelines for Chlorinated Dioxin/Furan Data Review dated August 2002*," the method specified criteria from USEPA Method 1613B, and professional judgment.

A detailed evaluation of the associated samples collected February 13, 2003 is presented in the following sections.

1.0 System performance Quality control Review

USEPA Method 1613B requires the use of HRGC/HRMS to detect and quantitate PCDD/PCDF. The high-resolution capillary column DB-5 was used for all analyses. Analytical results were reported to the estimated detection limit (EDL).

1.1 System Performance Check

Each instrument used for USEPA Method 1613B analysis was tuned using calibrant perfluorokerosene (PFK) for mass calibration and mass spectrometer resolution greater than or equal to 10,000, selective ion monitoring (SIM) scan descriptor switching times, and GC resolution. A system performance check was provided for each 12 hour analysis period, and for each instrument used during analysis. HRGC/HRMS instrument MAT95S/M2A was used to analyze the field samples and associated batch QC.

1.2 Initial Calibrations

Initial calibrations were reviewed for the instrument used for STL Report H3B140161. A five point initial calibration was performed by STL on the instrument. The following initial calibrations were reviewed: 9/12-13/02. The percent relative standard deviations (%RSDs), relative response factors (RRFs), signal to noise (S/N), retention time windows, and ion abundance ratios were reviewed against the method specified criteria. The associated initial calibrations were acceptable.

1.3 Continuing Calibrations

A continuing calibration (mid level standard) was analyzed prior to and following sample analysis. Less than the standard 12 hour analytical period was used. The continuing calibration was reviewed for each instrument RRFs, percent differences (%D), ion-abundance ratios, internal standard, and recovery compound, and was acceptable. The following continuing calibrations were reviewed in association with STL Report H3B140161: t 030227s1 associated with Method Blank, Laboratory Control Sample (LCS), PHII EFF (2/13/03)D, and PHII EFF (2/13/03)T. All continuing calibrations associated with STL Report H3B140161 were acceptable.

1.4 Method Blanks

Method blank (FHX421AA) was extracted with the field samples in STL Report H3B140161. In accordance with the "Data Validation Standard Operating Procedures for Chlorinated Dioxin/Furan Analysis by High-Resolution Gas Chromatography/High-Resolution Mass Spectrometry, USEPA Region IV, Revision 3.0, dated May 2002," and "USEPA Analytical Operations/Data Quality Center (AOC) National Functional Guidelines for Chlorinated Dioxin/Furan Data Review dated August 2002," any target analyte detected in the associated method blank is evaluated against the associated field samples by multiplying the blank concentration by five times (action level). The associated field sample data values reported less than the Action Level are qualified as "U/Not Detected," inclusive of those values reported at the EDL or estimated maximum possible concentration (EMPC). All values detected in the method blank were less than the target

detection limit (Section 2.3 of this evaluation) and therefore, the method blank is determined to be acceptable. OCDD was detected in samples PHII EFF (2/13/03)T and PHII EFF (2/13/03)D at concentrations (5.2 and 3.5 picograms per liter (pg/L), respectively) less than five times the concentration detected in the method blank (6.1 pg/L). Therefore, all detected sample compounds for this report were assigned the value NOT Detected.

1.5 Rinsate Blanks

A rinsate blank, field QC sample was not collected in associated with samples reported in STL Report H3B140161.

1.6 Matrix Spikes/Matrix Spike Duplicates (MS/MSD)

Additional sample volume of the samples was not supplied for MS/MSD analyses. Method accuracy was demonstrated though the analysis of a LCS.

1.7 Laboratory Control Sample (LCS)

One LCS (file FHX421AC) was extracted in association with the field samples analyzed in STL Report H3B140161. All recoveries were reviewed against the in-house control limit criteria for LCS recovery. The LCS accuracy data was acceptable.

1.8 Duplicate Analyses

Additional sample volume of the samples was not supplied for duplicate sample analyses. The samples presented were duplicates with one being filtered and one not. But, because all compounds were considered non-detect, precision cannot be determined.

2.0 Sample Review

STL Report H3B140161 contained samples PHII EFF (2/13/03)D, and PHII EFF (2/13/03)T, collected on February 13, 2003.

2.1 Holding Time

The chain-of-custody form was properly completed and signed and the groundwater sample was received in good condition and properly preserved at 4 degrees centigrade. The samples were extracted and analyzed within holding times.

2.2 Compound Identification

Sample results were reviewed against the method specific criteria for compound identification. Laboratory performance was acceptable.

All of the detected compounds were lower than five times the method blank detected levels. Therefore, all detected sample compounds were assigned the value NOT Detected.

2.3 Reporting

Target detection limits for USEPA Method 1613B are as follows for aqueous matrix:

≤ 10 pg/L TCDD & TCDF
≤ 50 pg/L Pent – Hepta CDD & CDF
≤ 100 pg/L OCDD & OCDF

The laboratory reported EDL, presented on the analytical reports as the detection limit (DL), which represents the maximum possible concentration of a target analyte that could be present without being detected. The EDL was reported for non-detected values less than the method target detection limit and were calculated for each field sample.

2.4 Internal Standards

Fifteen internal standards are required by USEPA Method 1613B. All 15 labeled internals, surrogates, and alternate standards were reviewed against a control limit criteria of 40-130 percent recovery. STL has established in-house criteria. All labeled standards were reviewed for each of the associated field samples and found to be acceptable with the following exceptions:

None

3.0 Overall Data Assessment

The evaluation of data quality was performed using the following Guidance documents "Data Validation Standard Operating Procedures for Chlorinated Dioxin/Furan Analysis by High-Resolution Gas Chromatography/High-Resolution Mass Spectrometry, USEPA Region IV, Revision 3.0, dated May 2002," and "USEPA Analytical Operations/Data Quality Center (AOC) National Functional Guidelines for Chlorinated Dioxin/Furan Data Review dated August 2002," the method specified criteria from USEPA Method 1613B, and professional judgment. The field sample data for STL Report H3B140161 are presented in Attachment A. No data were rejected. OCDD was detected in samples PHII EFF (2/13/03)T and PHII EFF (2/13/03)D at concentrations (5.2 and 3.5 pg/L, respectively) less than five times the concentration detected in the method blank (6.1 pg/L). Therefore, all detected sample compounds for this report were assigned the value NOT Detected. No other compounds were detected in either of these samples.

Subject:
Dioxin Data Validation Samples Collected January 22, 2003, at Kingsford, Michigan

ARCADIS Geraghty & Miller Project No.:
WI000975.0021

This report summarizes the review and evaluation of the January 22, 2003 samples WWTP EFF and PHII EFF collected in Kingsford, Michigan. Samples were submitted to Severn Trent Laboratories (STL), Inc., in Knoxville, Tennessee for the analysis of Polychlorinated Dibenzodioxins (PCDDs) and Polychlorinated Dibenzofurans (PCDFs) using United States Environmental Protection Agency (USEPA) Method 1613 Revision B (USEPA Method 1613B) (October 1994). This method uses high-resolution gas chromatography/high-resolution mass spectrometry (HRGC/HRMS). Samples collected on January 22, 2003 were received by STL on January 24, 2003, and were assigned the STL project number H3A300238.

Samples WWTP EFF and PHII EFF were collected on January 22, 2003. Sample WWTP EFF was a composite of samples collected from three different times. Both the WWTP and PHII samples had a second portion filtered and analyzed. A total of four samples were analyzed. All samples were extracted February 3, 2003 and analyzed on February 11, 2003.

The evaluation of data quality was performed using the guidance documents entitled: "*Data Validation Standard Operating Procedures for Chlorinated Dioxin/Furan Analysis by High-Resolution Gas Chromatography/High-Resolution Mass Spectrometry, USEPA Region IV, Revision 3.0, dated May 2002*," and "*USEPA Analytical Operations/Data Quality Center (AOC) National Functional Guidelines for Chlorinated Dioxin/Furan Data Review dated August 2002*," the method specified criteria from USEPA Method 1613B, and professional judgment.

A detailed evaluation of the associated samples collected January 22, 2003 is presented in the following sections.

1.0 System performance Quality control Review

USEPA Method 1613B requires the use of HRGC/HRMS to detect and quantitate PCDD/PCDF. The high-resolution capillary column DB-5 was used for all analyses. Analytical results were reported to the estimated detection limit (EDL).

1.1 System Performance Check

Each instrument used for USEPA Method 1613B analysis was tuned using calibrant perfluorokerosene (PFK) for mass calibration and mass spectrometer resolution greater than or equal to 10,000, selective ion monitoring (SIM) scan descriptor switching times, and GC resolution. A system performance check was provided for each 12 hour analysis period, and for each instrument used during analysis. HRGC/HRMS instrument MAT95S was used to analyze the field samples and associated batch QC.

1.2 Initial Calibrations

Initial calibrations were reviewed for each of the instruments used for STL Report H3A300238. A five point initial calibration was performed by STL on the instrument. The following initial calibrations were reviewed: 9/12-13/02. The percent relative standard deviations (%RSDs), relative response factors (RRFs), signal to noise (S/N), retention time windows, and ion abundance ratios were reviewed against the method specified criteria. The associated initial calibrations were acceptable.

1.3 Continuing Calibrations

A continuing calibration (mid level standard) was analyzed prior to and following sample analysis. Less than the standard 12 hour analytical period was used. The continuing calibration was reviewed for each instrument RRFs, percent differences (%D), ion-abundance ratios, internal standard, and recovery compound, and was acceptable. The following continuing calibrations were reviewed in association with STL Report H3A300238: t 030211s2 associated with Method Blank, Laboratory Control Sample (LCS), PHII EFF (1/22/03)D, PHII EFF (1/22/03)T, WWTP EFF (1/22/03)T, and WWTP EFF (1/22/03)D. All continuing calibrations associated with STL Report H3A300238 were acceptable.

1.4 Method Blanks

Method blank (FG2X61AA) was extracted with the field samples in STL Report H3A300238. In accordance with the "Data Validation Standard Operating Procedures for Chlorinated Dioxin/Furan Analysis by High-Resolution Gas Chromatography/High-Resolution Mass Spectrometry, USEPA Region IV, Revision 3.0, dated May 2002," and "USEPA Analytical Operations/Data Quality Center (AOC) National Functional Guidelines for Chlorinated Dioxin/Furan Data Review dated August 2002," any target analyte detected in the associated method blank is evaluated against the associated field samples by multiplying the blank concentration by five times (action level). The associated field sample data values reported less than the Action Level are qualified as "U/Not Detected," inclusive of those values reported at the EDL or estimated maximum possible concentration (EMPC). All values detected in the method blank were less than the target

detection limit (Section 2.3 of this evaluation) and therefore, the method blank is determined to be acceptable. OCDD was detected in samples PHII EFF (1/22/03)T, PHII EFF (1/22/03)D, WWTP EFF (1/23/03)T, and WWTP EFF (1/23/03)D at concentrations (9.8, 7.0, 12, and 3.2 picograms per liter (pg/L), respectively) less than five times the concentration detected in the method blank (7.7 pg/L). OCDF was detected in the sample PHII EFF (1/22/03)D at a concentration (4.0 pg/L) that was less than five times the concentration in the method blank (5.7 pg/L). Therefore, all detected sample compounds for this report were assigned the value NOT Detected.

1.5 Rinsate Blanks

A rinsate blank, field QC sample was not collected in associated with samples reported in STL Report H3A300238.

1.6 Matrix Spikes/Matrix Spike Duplicates (MS/MSD)

Additional sample volume of the samples was not supplied for MS/MSD analyses. Method accuracy was demonstrated though the analysis of a LCS.

1.7 Laboratory Control Sample (LCS)

One LCS (file FG2X61AC) was extracted in association with the field samples analyzed in STL Report H3A300238. All recoveries were reviewed against the in-house control limit criteria for LCS recovery. The LCS accuracy data was acceptable.

1.8 Duplicate Analyses

Additional sample volume of the samples was not supplied for duplicate sample analyses. The samples presented were duplicates with one being filtered and one not. But, because all compounds were considered non-detect, precision cannot be determined.

2.0 Sample Review

STL Report H3A300238 contained samples PHII EFF (1/22/03)D, PHII EFF (1/22/03)T, WWTP EFF (1/22/03)T, and WWTP EFF (1/22/03)D collected on January 22, 2003.

2.1 Holding Time

The chain-of-custody form was properly completed and signed and the groundwater sample was received in good condition and properly preserved at 4 degrees centigrade. The samples were extracted and analyzed within holding times.

(1/22/03)D, WWTP EFF (1/23/03)T, and WWTP EFF (1/23/03)D at concentrations (9.8, 7.0, 12, and 3.2 pg/L, respectively) less than five times the concentration detected in the method blank (7.7 pg/L). OCDF was detected in the sample PHII EFF (1/22/03)D at a concentration (4.0 pg/L) that was less than five times the concentration in the method blank (5.7 pg/L). Therefore, all detected sample compounds for this report were assigned the value NOT Detected. No other compounds were detected in either of these samples.

Subject:
Dioxin Data Validation Samples Collected March, 2003, at Kingsford, Michigan

ARCADIS Geraghty & Miller Project No.:
WI000975.0021

This report summarizes the review and evaluation of the March 4, 2003 samples PHII EFF collected in Kingsford, Michigan. Samples were submitted to Severn Trent Laboratories (STL), Inc., in Knoxville, Tennessee for the analysis of Polychlorinated Dibenzodioxins (PCDDs) and Polychlorinated Dibenzofurans (PCDFs) using United States Environmental Protection Agency (USEPA) Method 1613 Revision B (USEPA Method 1613B) (October 1994). This method uses high-resolution gas chromatography/high-resolution mass spectrometry (HRGC/HRMS). Samples collected on March 4, 2003 were received by STL on March 5, 2003, and were assigned the STL project number H3C050164.

The PHII EFF sample had a second portion filtered and analyzed. A total of two samples were analyzed. Both samples were extracted March 7, 2003 and analyzed on March 26, 2003.

The evaluation of data quality was performed using the guidance documents entitled: "*Data Validation Standard Operating Procedures for Chlorinated Dioxin/Furan Analysis by High-Resolution Gas Chromatography/High-Resolution Mass Spectrometry, USEPA Region IV, Revision 3.0, dated May 2002*," and "*USEPA Analytical Operations/Data Quality Center (AOC) National Functional Guidelines for Chlorinated Dioxin/Furan Data Review dated August 2002*," the method specified criteria from USEPA Method 1613B, and professional judgment.

A detailed evaluation of the associated samples collected March 4, 2003 is presented in the following sections.

1.0 System performance Quality control Review

USEPA Method 1613B requires the use of HRGC/HRMS to detect and quantitate PCDD/PCDF. The high-resolution capillary column DB-5 was used for all analyses. Analytical results were reported to the estimated detection limit (EDL).

1.1 System Performance Check

Each instrument used for USEPA Method 1613B analysis was tuned using calibrant perfluorokerosene (PFK) for mass calibration and mass spectrometer resolution greater than or equal to 10,000, selective ion monitoring (SIM) scan descriptor switching times, and GC resolution. A system performance check was provided for each 12 hour analysis period, and for each instrument used during analysis. HRGC/HRMS instrument MAT95S/M2A was used to analyze the field samples and associated batch QC.

1.2 Initial Calibrations

Initial calibrations were reviewed for the instrument used for STL Report H3C050164. A five point initial calibration was performed by STL on the instrument. The following initial calibrations were reviewed: 9/12-13/02. The percent relative standard deviations (%RSDs), relative response factors (RRFs), signal to noise (S/N), retention time windows, and ion abundance ratios were reviewed against the method specified criteria. The associated initial calibrations were acceptable.

1.3 Continuing Calibrations

A continuing calibration (mid level standard) was analyzed prior to and following sample analysis. Less than the standard 12 hour analytical period was used. The continuing calibration was reviewed for each instrument RRFs, percent differences (%D), ion-abundance ratios, internal standard, and recovery compound, and was acceptable. The following continuing calibrations were reviewed in association with STL Report H3C050164: t 030325s4 associated with Method Blank, Laboratory Control Sample (LCS), PHII EFF (3/04/03)D, and PHII EFF (3/04/03)T. All continuing calibrations associated with STL Report H3C050164 were acceptable.

1.4 Method Blanks

Method blank (FJQ9A1AA) was extracted with the field samples in STL Report H3C050164. In accordance with the "Data Validation Standard Operating Procedures for Chlorinated Dioxin/Furan Analysis by High-Resolution Gas Chromatography/High-Resolution Mass Spectrometry, USEPA Region IV, Revision 3.0, dated May 2002," and "USEPA Analytical Operations/Data Quality Center (AOC) National Functional Guidelines for Chlorinated Dioxin/Furan Data Review dated August 2002," any target analyte detected in the associated method blank is evaluated against the associated field samples by multiplying the blank concentration by five times (action level). The associated field sample data values reported less than the Action Level are qualified as "U/Not Detected," inclusive of those values reported at the EDL or estimated maximum possible concentration (EMPC). All values detected in the method blank were less than the target

detection limit (Section 2.3 of this evaluation) and therefore, the method blank is determined to be acceptable. OCDD was detected in samples PHII EFF (3/04/03)T and PHII EFF (3/04/03)D at concentrations (9.0 and 4.8 picograms per liter (pg/L), respectively) less than five times the concentration detected in the method blank (9.5 pg/L). 1,2,3,4,7,8 HxCDF was detected in sample PHII EFF (3/04/03)D at a concentration (0.97 pg/L) less than five times the concentration detected in the method blank (1.8 pg/L). 1,2,3,6,7,8 HxCDF was detected in sample PHII EFF (3/04/03)D at a concentration (0.85 pg/L) less than five times the concentration detected in the method blank (1.2 pg/L). Therefore, all detected sample compounds for this report were assigned the value NOT Detected.

1.5 Rinsate Blanks

A rinsate blank, field QC sample was not collected in associated with samples reported in STL Report H3C050164.

1.6 Matrix Spikes/Matrix Spike Duplicates (MS/MSD)

Additional sample volume of the samples was not supplied for MS/MSD analyses. Method accuracy was demonstrated though the analysis of a LCS.

1.7 Laboratory Control Sample(LCS)

One LCS (file FJQ9A1AC) was extracted in association with the field samples analyzed in STL Report H3C050164. All recoveries were reviewed against the in-house control limit criteria for LCS recovery. The LCS accuracy data was acceptable.

1.8 Duplicate Analyses

Additional sample volume of the samples was not supplied for duplicate sample analyses. The samples presented were duplicates with one being filtered and one not. But, because all compounds were considered non-detect, precision cannot be determined.

2.0 Sample Review

STL Report H3C050164 contained samples PHII EFF (3/04/03)D, and PHII EFF (3/04/03)T, collected on March 4, 2003.

2.1 Holding Time

The chain-of-custody form was properly completed and signed and the groundwater sample was received in good condition and properly preserved at or below 4 degrees centigrade. The samples were extracted and analyzed within holding times.

2.2 Compound Identification

Sample results were reviewed against the method specific criteria for compound identification. Laboratory performance was acceptable.

All of the detected compounds were lower than five times the method blank detected levels. Therefore, all detected sample compounds were assigned the value NOT Detected.

2.3 Reporting

Target detection limits for USEPA Method 1613B are as follows for aqueous matrix:

≤ 10 pg/L TCDD & TCDF
≤ 50 pg/L Pent – Hepta CDD & CDF
≤ 100 pg/L OCDD & OCDF

The laboratory reported EDL, presented on the analytical reports as the detection limit (DL), which represents the maximum possible concentration of a target analyte that could be present without being detected. The EDL was reported for non-detected values less than the method target detection limit and were calculated for each field sample.

2.4 Internal Standards

Fifteen internal standards are required by USEPA Method 1613B. All 15 labeled internals, surrogates, and alternate standards were reviewed against a control limit criteria of 40-130 percent recovery. STL has established in-house criteria. All labeled standards were reviewed for each of the associated field samples and found to be acceptable with the following exceptions:

None

3.0 Overall Data Assessment

The evaluation of data quality was performed using the following Guidance documents "Data Validation Standard Operating Procedures for Chlorinated Dioxin/Furan Analysis by High-Resolution Gas Chromatography/High-Resolution Mass Spectrometry, USEPA Region IV, Revision 3.0, dated May 2002," and "USEPA Analytical Operations/Data Quality Center (AOC) National Functional Guidelines for Chlorinated Dioxin/Furan Data Review dated August 2002," the method specified criteria from USEPA Method 1613B, and professional judgment. The field sample data for STL Report H3C050164 are presented in Attachment A. No data were rejected. OCDD was detected in samples PHII EFF (3/04/03)T and PHII EFF (3/04/03)D at concentrations (9.0 and 4.8 pg/L, respectively) less than five times the concentration detected in the method blank (9.5 pg/L). 1,2,3,4,7,8 HxCDF was detected in sample PHII EFF (3/04/03)D at a concentration (0.97 pg/L) less than five times the concentration detected in the method blank (1.8 pg/L). 1,2,3,6,7,8 HxCDF was detected in sample PHII EFF (3/04/03)D at a concentration (0.85 pg/L) less than five times the concentration detected in the method blank (1.2 pg/L). Therefore, all detected sample compounds

for this report were assigned the value NOT Detected. No other compounds were detected in either of these samples.

Dear Mr. Saalfeld:

On behalf of Ford Motor Company (Ford) and The Kingsford Products Company, ARCADIS is proposing this sampling plan for polychlorinated dibenzo-p-dioxin (dioxins) and polychlorinated dibenzofuran (furans) in several monitoring wells along the Menominee River. The results of previous groundwater sampling for dioxin suggest false positive detections of dioxin may have been recorded for these wells, and additional sampling and analysis is warranted to resolve this issue.

In May 2000, the Michigan Department of Environmental Quality (MDEQ) collected groundwater samples for dioxin analysis from six monitoring wells, four of which were located in the vicinity of the Menominee River. ARCADIS supplemented the MDEQ dioxin program with groundwater sampling for analysis of dioxin in July and August 2000. Additional groundwater sampling for dioxin was also conducted in September and October 2000, and February 2001. To date, 19 groundwater samples have been collected and analyzed for dioxin from 16 monitoring wells along the Menominee River. The results of the dioxin analyses are included in the attached Table 1. However, several of the monitoring wells are not representative of groundwater conditions near the Menominee River, as these monitoring wells are located more than 500 feet away (specifically Monitoring Wells GM-5, GM-6, and GM-28A).

The results of the dioxin analyses for the groundwater indicate that dioxin was not detected in 11 of the groundwater samples. The dioxin detected in the eight remaining groundwater samples were all reported as estimated concentrations between the method detection limit and method quantification limit (QL), or were otherwise qualified. Triangle Laboratories, Inc. (Durham, North Carolina) conducted all of these dioxin analyses using United States Environmental Protection Agency (U.S. EPA) Method 8290.

2.6.1 - 6/6/03_2

Evaluation of the dioxin groundwater data shows a higher level of estimated dioxin detections in groundwater samples collected during August/September 2000 than on the other sampling dates, along with several inconsistencies in the dioxin sampling results, which suggest there may have been a quality control issue at Triangle Laboratories at this time (Table 1). For example, the groundwater sample collected from Monitoring Well GM-66B had no dioxin detections in July 2000, but several estimated dioxin detections below the QL were indicated in the August 2000 groundwater sample. The groundwater sample collected from Monitoring Well GM-64A in August 2000 contained estimated dioxin detections, but no detections were present in the groundwater sample collected from this monitoring well in October 2000. Likewise, groundwater samples collected from Monitoring Well GM-68, located at the southeastern corner of the site, during August and September 2000 showed inconsistent estimated dioxin detections. The dioxin results from Monitoring Well GM-68 have been included in Table 1 to demonstrate the date inconsistencies, although this well is not associated with the Menominee River. A copy of the groundwater dioxin analytical results is being submitted to the MDEQ under separate cover.

Based on the existing dioxin results for the groundwater collected from monitoring wells along the Menominee River, ARCADIS proposes to resample the groundwater from five monitoring wells. The recommended sampling locations include Monitoring Wells GM-5, GM-25C, GM-26C, GM-63A, and GM-66A. In addition, ARCADIS recommends using Severn Trent Laboratories (STL) of Knoxsville, Tennessee for the dioxin analysis. The dioxin analysis would be conducted using U.S. EPA Method 1613B. This laboratory and analytical method were recently used to evaluate the potential presence of dioxin associated with the Iron Mountain/Kingsford wastewater treatment plant.

The collection of groundwater samples for dioxin analysis will be conducted in accordance with the procedures described in the Remedial Investigation Report for the Ford/Kingsford site (ARCADIS, June 2002). The groundwater samples will be collected from the monitoring wells using low-flow purging and sampling techniques. A Bennet air-piston positive displacement pump (Model 1800) or a Masterflex peristaltic pump (Model L/S 7570-10) will be used to complete the low-flow purging and sampling. A YSI (Model 610 XL) water probe will be placed down the well casing or in a flow-through cell assembly to monitor temperature, pH, specific conductance, dissolved oxygen, and redox potential during the sampling activities. Water levels will also be monitored to ensure that unacceptable drawdown within the monitoring well does not occur.

The monitoring wells will be purged at a flowrate between 100 and 500 milliliters per minute. Following stabilization of the field parameters, the groundwater samples will be collected by filling the sample containers directly from the pump tubing at the

stabilized purging flowrate. Upon collection, the groundwater samples will be placed on ice in a cooler and submitted under appropriate chain-of custody protocol to STL.

Any sampling equipment not dedicated to a monitoring well will be decontaminated with detergent solution wash and distilled water, as well as a hexane rinse, prior to and between each sampling event. Any decontaminated sampling equipment will be stored in aluminum foil to prevent contamination from plastics or other organic wrappings. New silicone and polyethylene tubing will be used with the peristaltic pump for each sampling event and will be discarded following completion of the sampling. New, disposable latex gloves will be worn by the sampling personnel and discarded after each sampling event. The water extracted during the monitoring well purging and sampling activities will be contained in plastic buckets or steel drums and transported to the Phase II groundwater treatment system for appropriate treatment.

Following receipt of MDEQ approval, the proposed sampling activities will be scheduled. If you have any questions regarding the information provided with this letter, please contact the undersigned.

Sincerely,

ARCADIS G&M, Inc.

Mr. Daniel Musgrove
The Kingsford Products Company
7201 Adams Street
Willowbrook, IL 60521

Dear Mr. Miller and Mr. Musgrove:

Subject: Dioxin Characterization in Monitoring Wells along the Menominee River, Kingsford/Breitung Township Site, Kingsford, Michigan

The Michigan Department of Environmental Quality (MDEQ) has received the sampling proposal for the above subject site dated June 6, 2003, for the Dioxin Characterization in Monitoring wells along the Menominee River in Kingsford, Michigan. Your consultant, ARCADIS G&M, prepared the sampling proposal. I have reviewed the information, and have the following comments:

1) The sampling plan should be expanded to provide the MDEQ with splits of all groundwater samples collected. Please provide the MDEQ with a schedule (21 days prior to any field activities) so the appropriate arrangements can be made with our contract laboratory.

2) The sampling plan should be modified to document the QA procedures (e.g. collection and analysis of replicate samples and field and laboratory blanks) that will be followed by ARCADIS.

3) The sampling plan should be expanded to identify the detection and quantification levels that will be achieved by Stevern Trent Laboratories for each dioxin/furan congener analyzed.

ENVIRONMENT

Mr. Chris Austin
Michigan Department of Environmental Quality
1420 U.S. 2 West
Crystal Falls, MI 49920

Subject:
Response to MDEQ Correspondence Dated July 1, 2003, Dioxin Characterization in Monitoring Wells Along the Menominee River, Ford/Kingsford Site, Kingsford, Michigan.

Dear Mr. Austin:

ARCADIS, on behalf of Ford Motor Company (Ford) and The Kingsford Products Company (KPC), has received the Michigan Department of Environmental Quality (MDEQ) correspondence dated July 1, 2003 regarding the Ford/KPC dioxin characterization plan for monitoring wells along the Menominee River at the subject site (outlined in a letter dated June 6, 2003). This letter provides the additional information requested by MDEQ and clarification regarding the dioxin characterization plan.

As outlined in the document entitled *Sampling and Quality Assurance Plan, Appendix A, Remedial Investigation Work Plan for the Ford/Kingsford Site* dated July 1998, ARCADIS will collect one sample replicate and one field blank sample per every 10 or fewer groundwater samples. Laboratory method blanks are routinely run by the project laboratory for every groundwater sample submitted for dioxin analysis.

In addition, as indicated in the dioxin characterization sampling plan, Method 1613-B will be used for analysis of the dioxin/furans. The congener quantification levels for Method 1613-B and laboratory methodology information regarding congener detection levels are provided as an attachment to this letter.

Although ARCADIS does not agree that estimated dioxin/furan congener values detected below the quantification levels are quantifiable data as suggested by the MDEQ, any congener value above the detection limit will be included in one of the TEC calculations for the groundwater sample in accordance with previous dioxin submittals, an example of which is provided in the attached Table 1. The MDEQ has previously requested and approved this dioxin submittal format.

ARCADIS, on behalf of Ford/KPC, plans to initiate the proposed dioxin characterization plan in August/September 2003. Per your request, ARCADIS will notify MDEQ at least 21 days prior to the groundwater sampling activities.

Date:
1 August 2003

Appendix 1

Method 8290 and 1613B reference the Minimum Level (ML). The qualitative definition of the ML is "the lowest level at which the analytical system must give a reliable signal and an acceptable calibration point". The ML was introduced in EPA Methods 1624 and 1625 in 1980 and was promulgated in these methods in 1984 at 40 CFR Part 136, Appendix A.
The USEPA Engineering and Assessment Division has established guidance for setting the ML which is a level set 2-3 times the *interlaboratory method mdls* established for the methods during validation.
Unlike the way 40 CFR Part 136A is often used (i.e., as a measure of individual laboratory performance) the MLs established for 8290 and 1613 were established from data at multiple laboratories to assess method performance.
The lab will report all detections down to the smallest allowable peaks (i.e., 2.5 times the average noise for 3 consecutive scans). The Estimated Detection Limit (EDL) is also provided for each analyte. This is a value calculated to estimate the concentration in the sample that would meet the minimum signal-to-noise requirement (2.5 times the intensity of the average noise level). The EDL does not exactly equal the smallest amount reported. This is primarily due to differences in the way the two values are calculated. The EDL is calculated using peak intensity, whereas the sample concentration is calculated on the basis of area. The ratio between the two varies with concentration.
Any detections below the ML are qualified by a J flag.

Estimated Detection Limits

If no peaks are present in the region of the ion chromatogram where the compounds of interest are expected to elute, the EDL for that compound is calculated and reported. The EDL reflects the amount of the particular analyte that would be required to cause a positive result for the particular analysis.

The EDL is calculated according to the following equation:

$$\text{Estimated Detection Limit} = \frac{N \times 2.5 \times Qis}{His \times RRF \times W \times S}$$

where:

N	=	peak to peak noise of quantitation ion signal in the region of the ion chromatogram where the compound of interest is expected to elute
His	=	peak height of quantitation ion for appropriate internal standard
Qis	=	ng of internal standard added to sample
RRF	=	mean relative response factor of compound obtained during initial calibration
W	=	amount of sample extracted (grams or liters)
S	=	percent solids (optional, if results are requested to be reported on dry weight basis)

Appendix 2

J – The reported result is an estimate. The amount reported is below the Minimum Level (ML). The qualitative definition of the ML is "the lowest level at which the analytical system must give a reliable signal and an acceptable calibration point". The ML was introduced in EPA Methods 1624 and 1625 in 1980 and was promulgated in these methods in 1984 at 40 CFR Part 136, Appendix A. For the purposes of this report the ML is qualitatively defined as described above, and quantitatively defined as follows:
Minimum Level: The concentration or mass of analyte in the sample that corresponds to the lowest calibration level in the initial calibration. It is the sample concentration which results in an extract concentration equal to the lowest calibration standard, after corrections for sample weights/volumes, extract splitting and dilutions have been employed.
Example: The lowest calibration level for TCDD in the initial calibration is 0.5 pg/uL. A mass of 10 pg of 2,3,7,8-TCDD in the sample would result in a concentration of 0.5 pg/uL in the sample extract (at a final volume of 20 uL). Since the concentration in the sample extract corresponds to the concentration in the lowest calibration standard, the 10 pg mass in the sample components is the ML. If the sample extract is further diluted, the ML will increase by the dilution factor.
Example: A 1/10 dilution is performed on the sample extract described above. The ML for 2,3,7,8-TCDD becomes 100 pg rather than the default of 10 pg.
E – The reported result is an estimate. The amount reported is above the UCL described below.
The E qualifier is applied based on the **Upper Calibration Level (UCL)**. The quantitative definition of the UCL is listed below:
The concentration or mass of analyte in the sample that corresponds to the highest calibration level in the initial calibration. It is the sample concentration which results in an extract concentration equal to the highest calibration standard, after corrections for sample weights/volumes, extract splitting and dilutions have been employed.
Example: The highest calibration level for TCDD in the initial calibration is 200 pg/uL. A mass of 4000 pg of 2,3,7,8-TCDD in the sample would result in a concentration of 200 pg/uL in the sample extract (at a final volume of 20 uL). Since the concentration in the sample extract corresponds to the concentration in the highest calibration standard, the 4000 pg mass in the sample components is the UCL. If the sample extract is further diluted, the ML will increase by the dilution factor.
Example: A 1/10 dilution is performed on the sample extract described above. The UCL for 2,3,7,8-TCDD becomes 40000 pg rather than the default of 4000 pg.

Dear Mr. Austin:

In accordance with your request of September 26, 2003, ARCADIS is submitting this document on behalf of Ford Motor Company (Ford) and The Kingsford Products Company (KPC), to provide the most recent results of the subject analyses. Monitoring of Groundwater Extraction Wells GMEW-1, GMEW-2, GMEW-3, GMEW-4R, and treated effluent from the Groundwater Pretreatment System (System) located at 2241 West Breitung Avenue was performed in January, February, March, and June 2003 for polychlorinated dibenzo-p-dioxins (dioxins) and polychlorinated dibenzofurans (furans). The results of the January, February, and March 2003 sampling were previously submitted to the Michigan Department of Environmental Quality (MDEQ) in a letter report dated June 2, 2003.

On June 26, 2003, ARCADIS collected samples from Extraction Wells GMEW-1, GMEW-2, GMEW-3, GMEW-4R, and the System effluent. The samples were submitted to Severn Trent Laboratories, Inc. (STL), Knoxville, Tennessee, for analysis of dioxins and furans (total and dissolved) using United States Environmental Protection Agency Method 1613, Revision B *"Tetra- through Octa-Chlorinated Dioxins and Furans by Isotope Dilution HRGC/HRMS"* (October 1994). The monitoring event consisted of collecting a grab sample from each location, consistent with the sampling methods approved by MDEQ. The contribution of flow from each of the extraction wells to the System 8 days prior to, and 4 days after each sampling event is provided in Table 1. As seen in the table, flowrates were consistent throughout the sampling.

The results of the dioxin and furan sampling and analyses indicate that there are no detectable concentrations of dioxins or furans in the System effluent or the groundwater pumped from Extraction Wells GMEW-1, GMEW-2, GMEW-3, and GMEW-4R. All toxicity equivalence concentration (TEC) results are zero and detection limits are well below U.S. Environmental Protection Agency and MDEQ Target Detection Limits and Quantification Limits. Results are summarized in

2.6.1.34 - 10/10/03

Tables 2 through 4. The data presented in Tables 3 and 4 were validated by ARCADIS and the validation reports are provided in Attachment A. The laboratory reports generated by STL will be transmitted to the MDEQ under separate cover by ARCADIS.

Ford, KPC, and ARCADIS appreciate MDEQ's cooperation on this issue. Should you have any questions regarding this submittal, please contact me at (414) 277-6225.

Sincerely,

ARCADIS G&M, Inc.

Richard L. Studebaker, Jr., PE
Senior Engineer/Project Manager

* Dioxin sample was collected from either the system effluent or the extraction wells.

gal Gallon

gpm Gallon per minute.

(1) Daily flow (gal) is the arithmetic sum of the daily flow (gal) of each extraction well. Daily flow (gpm) is the average flowrate over 24 hours (e.g. 32,500 gal/1,440 minutes/day = 23 gpm).

All values are reported in parts per quadrillion (ppq).

(ND) Detected result was qualified as "not detected" due to associated blank contamination; contribution to the TEC is zero.
BEF Bioaccumulation equivalency factor [MDEQ, Rule 323.1209(4)(ii)].
DL Detection limit.
ND Congener was not detected; contribution to the TEC is zero.
ppq Parts per quadrillion (picograms per liter).
QL Congener quantification level.
TEC Toxicity equivalence concentration of 2,3,7,8-TCDD.
TEF Toxicity equivalency factor [MDEQ, Rule 323.1209(4)(ii)].

* TEC (ppq) = Detected result (ppq) × BEF × TEF

Data Qualifiers:

B Compound was detected in the associated QC method blank sample.
E Estimated maximum possible concentration.
J Concentration is qualified as estimated.
K Concentration exceeds the calibration curve; qualified as estimated.
U Result was qualified as "not detected" during data validation.
Q Estimated maximum possible concentration.

All values are reported in parts per quadrillion (ppq).

(ND) Detected result was qualified as "not detected" due to associated blank contamination; contribution to the TEC is zero.

BEF Bioaccumulation equivalency factor [MDEQ, Rule 323.1209(4)(ii)].

DL Detection limit.

* TEC (ppq) = Detected result (ppq) × BEF × TEF

ND Congener was not detected; contribution to the TEC is zero.

ppq Parts per quadrillion (picograms per liter).

QL Congener quantifical limit for that sample.

TEC Toxicity equivalence concentration of 2,3,7,8-TCDD.

TEF Toxicity equivalency factor [MDEQ, Rule 323.1209(4)(ii)].

Data Qualifiers:

B Compound was detected in the associated QC method blank sample.

E Estimated maximum possible concentration.

J Concentration is qualified as estimated.

K Concentration exceeds the calibration curve; qualified as estimated.

U Result was qualified as "not detected" during data validation.

Q Estimated maximum possible concentration.

MEMORANDUM

To:
Ric Studebaker

Copies:

ENVIRONMENT

From:
Libby Nessley

Date:
September 3, 2003

Subject:
Dioxin Data Validation Samples Collected June 26, 2003 Kingsford, Michigan

ARCADIS Geraghty & Miller Project No.:
WI000975.0021

This report summarizes the review and evaluation of eight samples collected June 26, 2003 in Kingsford, Michigan. This includes the following samples:

- GMEW-1 (6/26/03)T
- GMEW-2 (6/26/03)T
- GMEW-3 (6/26/03)T
- GMEW-4R (6/26/03)T
- GMEW-1 (6/26/03)D
- GMEW-2 (6/26/03)D
- GMEW-3 (6/26/03)D
- GMEW-4R (6/26/03)D

Samples were submitted to Severn Trent Laboratories (STL), Inc., in Knoxville, Tennessee for the analysis of Polychlorinated Dibenzodioxins (PCDDs) and Polychlorinated Dibenzofurans (PCDFs) using United States Environmental Protection Agency (USEPA) Method 1613 Revision B (USEPA Method 1613B) (October 1994). This method uses high-resolution gas chromatography/high-resolution mass spectrometry (HRGC/HRMS). Grab samples collected on June 26, 2003 were received by STL on June 27, 2003, and were assigned the STL project number H3F270267. The samples with the T designation represent total samples and those with the D designation were laboratory filtered prior to extraction and analysis. Samples were extracted on July 7, 2003 and analyzed on July 15, 2003. USEPA Method 1613B requires the use of HRGC/HRMS to detect and quantitate PCDD/PCDF. The high-resolution capillary column DB-5 was used for all analyses. Analytical results were reported to the estimated detection limit (EDL).

The evaluation of data quality was performed using the guidance documents entitled: "*Data Validation Standard Operating Procedures for Chlorinated Dioxin/Furan Analysis by High-Resolution Gas Chromatography/High-Resolution Mass Spectrometry, USEPA Region IV, Revision 3.0, dated May 2002*," and "*USEPA Analytical Operations/Data Quality Center (AOC) National Functional Guidelines for Chlorinated Dioxin/Furan Data Review dated August 2002*," the method specified criteria from USEPA Method 1613B, and professional judgment.

A detailed evaluation of the associated samples collected June 26, 2003 is presented in the following sections.

1.0 Holding Times, Storage and Preservation

The chain-of-custody form was properly completed and signed. The groundwater samples were received in good condition and properly preserved at 4 degrees centigrade. The samples were extracted and analyzed within holding times of 30 and 45 days, respectively.

2.0 Performance Evaluation Samples

No performance evaluation samples were included with this delivery group. Method accuracy was determined through the analysis of a laboratory control sample (LCS).

3.0 Mass Calibration and Mass Spectrometer Resolution

The instrument used for USEPA Method 1613B analysis was tuned using calibrant perfluorokerosene (PFK) for mass calibration and mass spectrometer resolution greater than or equal to 10,000, selective ion monitoring (SIM) scan descriptor switching times, and GC resolution. A system performance check was provided for each 12-hour analysis period, and for the instrument used during analysis. HRGC/HRMS instrument MAT95S was used to analyze the field samples and associated batch QC. All system performance checks met the mass spectrometer resolution requirement of >10,000.

4.0 Window Defining Mix

The Window Defining Mix (WDM), a standard solution composed of the first and last eluting dioxin and furan isomers used to define the beginning and ending retention times, was run at the required frequency. Retention times for identified compounds were within the established windows.

5.0 Chromatographic Resolution

Review of the chromatographic peak separation between the 2,3,7,8-TCDD peak and the 1,2,3,8-TCDD peak showed a resolution valley within the criteria of <25%.

6.0 Instrument Stability

All criteria for absolute and relative retention times, ion abundance ratios, instrument sensitivity and relative response were met.

7.0 HRGC/HRMS Initial Calibration

Initial calibration was reviewed for the instrument used for STL Report H3F270267. A five point initial calibration was performed by STL on the instrument. The following initial calibration was reviewed: 4/1/03. The percent relative standard deviations (%RSDs), relative response factors (RRFs), signal to noise (S/N), retention time windows, and ion abundance ratios were reviewed against the method specified criteria. The associated initial calibration was acceptable.

8.0 HRGC/GRMS Calibration Verification

Continuing calibrations (mid level standard) were analyzed prior to and following sample analysis. The continuing calibrations were performed more frequently than the minimum mandated by the method (e.g. each 12-hour analytical period). The continuing calibrations were reviewed for instrument RRFs, percent differences (%D), ion-abundance ratios, internal standard, and recovery compound, and were acceptable. The following continuing calibrations were reviewed in association with STL Report H3F270267: t030714S2, t030715S2 and t030715S3. All continuing calibrations associated with STL Report H3F270267 were acceptable.

9.0 Identification Criteria

Sample results were reviewed against the method specific criteria for compound identification. Laboratory performance was acceptable. Compound identifications qualified with "Q" flags (indicating the estimated maximum possible concentration (EMPCs)) were individually evaluated by the reviewer for signal-to-noise, retention time and ion abundance criteria. Professional judgment was used to determine whether the flagged compounds were positively identified or not detected.

Detected compounds at concentrations lower than five times the method blank detected levels were qualified as "U"/NOT Detected in all samples except sample GMEW-4R (6/26/03)D. This sample had a reported EMPC of 1,2,3,4,6,7,8 HpCDF (1.4 Q,J pg/L). This compound, however, did not meet Method 1613 ion abundance criteria using peak area or peak height (as allowed in the Functional Guidelines, Part IX, Section C.4). Therefore, this compound is not identified and the result is not reported as stated in Method 1613, Section 16.6. For this reason, this compound is qualified with a "U"/NOT Detected. Sample results and the associated qualifiers are summarized in Table 1.

10.0 Method Blank

Method blank (FRR911AA) was extracted with the field samples in STL Report H3F270267. In accordance with the "Data Validation Standard Operating Procedures for Chlorinated Dioxin/Furan Analysis by High-Resolution Gas Chromatography/High-Resolution Mass Spectrometry, USEPA Region IV, Revision 3.0,

dated May 2002," and "USEPA Analytical Operations/Data Quality Center (AOC) National Functional Guidelines for Chlorinated Dioxin/Furan Data Review dated August 2002," any target analyte detected in the associated method blank is evaluated against the associated field samples by multiplying the blank concentration by five times (action level). The associated field sample data values reported less than the Action Level are qualified as "U/Not Detected," inclusive of those values reported at the EDL or estimated maximum possible concentration (EMPC). The following compounds were reported in the Method Blank: 1,2,3,7,8,9-HxCDD (5.8J pg/L); 1,2,3,4,6,7,8-HpCDD (3.4J pg/L); OCDD (9.3Q, J pg/L); 2,3,4,6,7,8-HxCDF (2.9J pg/L) and OCDF (8.4J pg/L). The OCDD peak was flagged "Q" by the laboratory for falling slightly outside ion abundance criteria for peak area. The peak integration was evaluated and ion abundance criteria using peak height was met. In the reviewer's professional judgment, the laboratory "Q" flag should be dropped from this compound.

All values detected in the method blank were less than the target detection limit (Section 12 of this evaluation) and therefore, the method blank is determined to be acceptable.

11.0 Laboratory Control Samples

One LCS (file FRR911AC) was extracted in association with the field samples analyzed in STL Report H3F270267. All recoveries were reviewed against the in-house control limit criteria for LCS recovery. The LCS accuracy data was acceptable. Raw data for a laboratory control sample duplicate (LCSD) was also included in the data package but not detailed in the summary report because analysis of an LCSD is not required by the Functional Guidelines. However, review of the LCSD data showed good agreement between the LCS and LCSD. Percent differences were all <5%.

12.0 Estimated Detection Limit and Estimated Maximum Possible Concentration

Target detection limits for USEPA Method 1613B are as follows for aqueous matrix:

≤ 10 pg/L TCDD & TCDF
≤ 50 pg/L Pent – Hepta CDD & CDF
≤ 100 pg/L OCDD & OCDF

The laboratory reported EDL, presented on the analytical reports as the detection limit (DL), which represents the maximum possible concentration of a target analyte that could be present without being detected. The EDL was reported for non-detected values less than the method target detection limit and were calculated for each field sample.

13.0 Labeled Compound Recoveries

Fifteen internal standards are required by USEPA Method 1613B. All 15 labeled internals, surrogates, and alternate standards were reviewed against a control limit criteria of 40-130 percent recovery. STL has established in-house criteria. All criteria were met for all samples.

14.0 Overall Data Assessment

The evaluation of data quality was performed using the following Guidance documents "Data Validation Standard Operating Procedures for Chlorinated Dioxin/Furan Analysis by High-Resolution Gas Chromatography/High-Resolution Mass Spectrometry, USEPA Region IV, Revision 3.0, dated May 2002," and "USEPA Analytical Operations/Data Quality Center (AOC) National Functional Guidelines for Chlorinated Dioxin/Furan Data Review dated August 2002," the method specified criteria from USEPA Method 1613B, and professional judgment. The field sample data for STL Report H3F270267 are presented in Attachment A. 1,2,3,4,6,7,8-HpCDF (1.4 Q,J) reported in sample GMEW-4R (6/26/03)D should have been reported by the laboratory as a non-detect, due to failure to meet ion abundance criteria for peak area and peak height. Other reported concentrations were all less than five times the concentration detected in the method blank. Therefore, the detected sample compounds for this report were assigned the value NOT Detected and qualified "U".

Table 1. Sample Results and Qualifier Summary

IDENTIFIED COMPOUNDS	LABORATORY REPORTED CONC. (pg/L)	ADDITIONAL QUALIFIERS	REASON
GMEW-1 (6/26/03)T

Mr. Gary Lessard
Iron Mountain-Kingsford WWTP
P.O. Box 88
Kingsford, MI 49802

Dear Mr. Lessard:

We have reviewed the dioxin and furan (dioxin) characterization reports provided by Arcadis on behalf of the Iron Mountain/Kingsford WWTP (IMK) and Ford/Kingsford (F/K) on May 29, 2003, and June 2, 2003, respectively. These data were reported as non-detect (ND) for all monitored dioxin congeners. Coupled with data from March 29, 2002, samples that report dioxin at levels of concern, the existing database does not clearly indicate that dioxins are not a chemical of concern at F/K and IMK.

Dioxin sampling and headworks analysis requirements were outlined in Ms. Kristen Mariuzza's letter of October 15, 2002. Dioxin treatability via headworks analysis at IMK WWTP, while accepting Phase II, was not possible due to dioxin being reported as ND in the recent submittals. For that reason, the DEQ will allow IMK WWTP and F/K to proceed to Phase III or remain at Phase II with the sampling stipulations and response/notification actions as described in the attached memo from Mr. Bruce Walker, DEQ Surface Water Quality Assessment Section (SWQAS). This monitoring program shall be initiated within 90 days of the receipt of this letter unless:

1) Demonstration, via a robust sampling program, is conducted according to a DEQ approved plan, that F/K site groundwaters and effluent do not contain unacceptable levels of dioxin, or;
2) The IMK WWTP notifies the Water Division Supervisor of the Upper Peninsula District in writing that the IMK no longer accepts the F/K site waters/effluent.

The IMK WWTP's National Pollutant Discharge Elimination System (NPDES) permit will be processed in the coming year and is scheduled to be issued by September 30, 2004. All existing and future dioxin data from IMK WWTP and F/K site sampling will be used in the NPDES permit renewal review. Inclusion of NPDES monitoring conditions is, at a minimum, to be expected if dioxin is detected in the IMK WWTP or F/K flows. If unacceptable levels of dioxin are present in the IMK effluent, dioxin limitations, monitoring conditions, and pollutant minimization plan requirements will be included in the next permit.

The conditional approval of Phase III flows is based upon the proposal described in an Arcadis document dated December 13, 2001, submitted to Water Division. If Phase III plans have changed, the DEQ would need Arcadis to submit a new proposal.

.6.1 - 11/5/03_2

In summary, within 90 days of receiving this letter, dioxin monitoring and reporting is required if IMK accepts Phase III F/K waters or continues to accept F/K Phase II waters. These monitoring conditions will not be required if DEQ is informed that F/K flows to IMK are terminated or if a robust, DEQ approved sampling program demonstrates F/K site waters and effluent flows do not contain unacceptable levels of dioxin.

Thank you for your continued cooperation. Please contact me with any questions, concerns or comments.

Sincerely,

Benjamin R. Thierry

TO: Ben Thierry, MDEQ, UP District

FROM: Bruce Walker, MEDQ, SWQAS, Lansing

SUBJECT: Iron Mountain/Kingsford WWTP and Ford/Kingsford Pilot Dioxin Characterization

We have reviewed the dioxin and furan (dioxin) characterization reports provided by Arcadis on behalf of the Iron Mountain/Kingsford WWTP (IMK) and Ford/Kingsford (F/K) on May 29 and June 2, 2003. The submittal dated May 29, 2003 included dioxin data for three IMK effluent composite samples collected during the period January to March, 2003. The submittal dated June 2, 2003 included dioxin data for three F/K Phase II effluent grab samples collected during the period January to March, 2003.

These data were provided in response to Kristen Mariuzza's October 15, 2002 letter to the IMK. That letter outlined the required headworks analysis associated with Phase II flows from the F/K pilot site to the IMK. The basis for generating these limited datasets was to provide a preliminary dioxin characterization of the IMK effluent while receiving F/K Phase II effluent, to hopefully provide data that would allow an IMK headworks and treatability analyses for dioxin, to provide additional data on potential F/K Phase II effluent dioxin discharges, and to provide information relative to potential IMK dioxin discharges under F/K Phase III conditions.

In the noted May and June 2003 submittals, the three IMK effluent samples only had the octa-substituted congeners reported as detected, which were also detected in the blanks, and the three F/K Phase II site effluent samples were reported as non-detect (ND) for all monitored congeners. Because of the ND results, the required Phase II headworks and treatability analysis was not possible. Water Division (WD) recognizes that the specified effort was made and, therefore, we suggest suspending the previous Phase II headworks analysis requirement until additional sampling and analysis are completed.

To gain the best overview of the potential dioxin related issues at the IMK, the data included in the May 29, 2003 and June 2, 2003 submittals were reviewed as well as the other dioxin data available for the IMK and the F/K site.

The larger F/K site Phase II dataset contained in the March 29, 2002 submittal indicated the presence of detectable dioxin congeners at levels of concern in a number of the well and site effluent samples. Some of the data in this submittal may reflect the apparently

2.6.1 - 11/5/03_1

viable pumping conditi[illegible]s at the F/K site. This 2002 dataset superficially may appear to show a different picture than that presented by the smaller 2003 datasets noted above but it is worth pointing out that some of the samples in the March 29, 2002 submittal were also reported as ND. The WD is of the opinion that the information in this larger dataset indicates the potential presence of dioxin at levels of concern in the F/K site groundwaters and effluents and, therefore, potentially at the IMK.

To address some questions raised about the data contained in these submittals, the DEQ Remediation and Redevelopment Division (RRD) had an outside review conducted on the data contained in the March 29, 2002, the May 30, 2003, and the June 2, 2003 submittals. The 2003 samples were analyzed by a different laboratory than that used for the prior samples. The review noted that some samples had detections for some congeners in the associated blanks, but concluded that the data packages in these submittals were of acceptable quality and the data from both laboratories were usable given the appropriate qualifications. This finding lends support to WD's interpretation of the existing dioxin database for the F/K site.

Additionally, during our review of the data in the June 2, 2003 submittal, we noted that the third bullet on page 2 of the submittal's cover letter discusses the issue of congener detections in blank samples. This bullet basically states that the F/K Phase II site effluent samples in the March 2002 submittal had more congener detections in the associated blanks than did the 2003 samples and more of the reported sample congener detections were therefore actually ND. The bullet then suggests that the 2003 data are therefore more accurate. It is not clear to us how the stated (22.5%) percent blank detection (and the "corrected' congener result of ND) calculation was done for the March 2002 submittal data. Our review of the March 2002 submittal dataset indicates that very few (< 5%) of the dioxin congeners reported as detected in either the F/K Phase II site effluent or groundwater samples had the same congener reported as detected in the associated blank.

Another set of F/K site dioxin groundwater data from May 2000 was also available for this review. These data, apparently the first groundwater dioxin sampling to occur at the F/K site, also included the reporting of some detected dioxin congeners at levels of concern.

Overall, our above review of the small, currently available IMK effluent dioxin data does not indicate the presence of detectable levels of dioxin in the IMK effluent under the site conditions present at the time of sampling. We wish to point out that theoretical IMK effluent limitations for dioxin are below current standard sampling and analytical methods. These limited effluent data suggest there is not a need to immediately modify the IMK permit. Therefore, we suggest that WD conditionally approve the IMK request to accept Phase III effluent from the F/K site (as described in a December 13, 2001, document submitted to WD by Arcadis).

The suggested WD approval for IMK to accept Phase III F/K site effluents is contingent upon IMK satisfying the monitoring requirements that are listed below. These monitoring conditions are necessary because the larger body of data reviewed indicate the potential for the presence of some dioxin congeners at levels of concern in the F/K site groundwaters and in the effluents that is generated as part of the pilot project which is pumping and treating a small portion of the extensive chemical plume at this site. Acceptance of these contaminated F/K site groundwaters or effluents as an IMK influent

stream creates a cond' n where dioxin potentially could be sent in the IMK effluent. This indicates that, during Phase III, there is a need to continue dioxin monitoring at IMK and to continue the tracking of dioxin at the F/K site. These monitoring requirements shall be accomplished via EPA Method 1613 for the 17 dioxin congeners currently assessed. As used below, the term "routine monitoring" means a sampling frequency of twice per month for water samples and once per month for sludge samples. Collection of the water samples (well, influent, and effluents) for this routine monitoring will be coordinated between the F/K and IMK sampling locations such that the temporal sequence of sample collection reflects the flow pattern and detention times present in these two systems (i.e. wells first and IMK effluent last).

IMK Dioxin Monitoring Requirements

A. Dioxin sampling at the IMK Facility.
   1) Routine monitoring via composite samples of both the combined IMK influent and the final effluent. Effluent sample collections shall be temporally spaced from the influent sample collections to account for detention times such that the effluent samples correspond to the associated influent samples.
   2) Routine monitoring of dewatered primary clarifier sludge, including percent solids data for each sample.

B. Dioxin sampling at the F/K Site.
   3) Routine monitoring of appropriate (to be determined in concert with RRD staff) F/K site groundwater extraction and monitoring wells. All wells pumping to the F/K site shall be sampled such that these samples correspond to the effluent sample as described in 4) below.
   4) Routine monitoring of the effluent from the F/K site treatment facility. As with the IMK sampling, the collection of effluent samples shall be temporally spaced from that of the well samples to account for detention times such that the effluent samples correspond to the associated site influent (i.e. well) samples.
   5) Routine monitoring of the sludge generated by the F/K site treatment facility, including percent solids data for each sample.

C. Reporting.
   6) The results from these monitoring activities shall be reported via a monthly report to the Water Division Supervisor of the Upper Peninsula District. The report shall include the congener specific data, including detection level data and appropriate associated quality assurance data for the individual samples, and a summary of that month's data. The data summary also shall include information on trends over time in dioxin concentration in the matrices monitored. The report shall be submitted within 30 days of receipt of the analytical results for the last sample in each monthly sampling period.

   7) If monitoring results show the presence of dioxin in the F/K site wells or effluent at concentrations which exceed Michigan Water Quality Standards (WQS), a robust headworks and treatability analysis for dioxin must be conducted by the IMK and submitted to the Water Division Supervisor of the Upper Peninsula District after IMK is notified in writing of the need for such an analysis. If the monitoring reveals quantified levels of dioxin above the WQS in the IMK effluent, the IMK shall notify the Water Division Supervisor of the Upper Peninsula District of this finding and immediately terminate acceptance of the F/K site waters and/or effluent. The WQS for the 2, 3, 7, 8-tetrachlorodibenzo-p-dioxin (2, 3, 7,

8-TCDD) congener and the 2, 3, 7, 8-TCDD toxicity equivalency concentration (TEC) are 0.003 ppg and 0.0086 ppq, respectively. If the monitoring reveals the presence of detectable levels of dioxin in the IMK effluent, the Department reserves the right to require additional monitoring and/or source control actions as warranted. These actions may include termination of IMK acceptance of F/K flows and/or conducting a robust headworks and treatability analysis for dioxin.

D. Reductions in monitoring.

8) After 6 months of Phase III data have been generated and submitted, the IMK may request a reduction in the monitoring frequency for any of the specified matrices or locations. No reduction in the specified monitoring shall occur unless authorized in writing by the Water Division Supervisor of the Upper Peninsula District. Additionally, upon written notification by the Water Division Supervisor of the Upper Peninsula District, the IMK dioxin monitoring conditions may be expanded as warranted by the available data or as the conditions change at the F/K site.

This monitoring program shall be initiated within 90 days of IMK receiving this letter unless:

1) the IMK notifies the Water Division Supervisor of the Upper Peninsula District in writing that the IMK no longer accepts the F/K site waters/effluent or;
2 the IMK can demonstrate, via a robust sampling program conducted according to a DEQ approved plan, that the F/K site groundwaters and effluent do not contain unacceptable levels of dioxin.

The IMK should recognize that all existing and future dioxin data for the IMK and F/K site matrices may be used during the review of the current IMK NPDES permit renewal application. The IMK also should be aware that the presence of unacceptable levels of dioxin in the monitored IMK or F/K site matrices will, at a minimum, likely trigger inclusion of NPDES permit monitoring conditions similar to those described above as well as the potential inclusion of additional appropriate permit conditions which could include numerical dioxin limitations.

In summary, we suggest that the MDEQ approve the IMK request to accept F/K Phase III effluent contingent upon IMK satisfying the dioxin monitoring and reporting requirements that are listed above. These conditions also apply to IMK acceptance of the F/K site Phase II effluent.

Subject:
Summary of Analyses for Dioxins and Furans, Ford/Kingsford Site, Kingsford, Michigan.

Dear Messrs. Dell and Saalfeld:

ARCADIS is pleased to submit this document on behalf of Ford Motor Company (Ford) and The Kingsford Products Company (KPC) to provide a summary of polychlorinated dibenzo-p-dioxins (dioxins) and polychlorinated dibenzofurans (furans) analyses for the subject site previously submitted to the Michigan Department of Environmental Quality (MDEQ). This document is submitted in accordance with the action items established during our Wednesday, November 12, 2003 meeting to discuss the preliminary National Pollutant Discharge Elimination System (NPDES) permit application for the full-scale groundwater treatment system proposed for the subject site. Historical monitoring data for dioxins/furans is presented from the following sample locations:

- Groundwater extraction wells located along the Menominee River at the subject site.
- Influent and effluent of the groundwater pretreatment system located at 2241 West Breitung Avenue in Kingsford, Michigan.
- Influent, effluent, and digester sludge from the Iron Mountain/Kingsford Wastewater Treatment Plant.

Sample collection during each monitoring event was completed in accordance with the sampling methods approved by MDEQ approved sampling methodologies.

In addition to the previously submitted data, this document provides data from the sampling conducted at Groundwater Monitoring Wells GM-5, GM-25C, GM-26C, GM-63A, and GM-66A on September 15, 2003. These data, recently validated, are presented herein for the first time (without the validation reports). ARCADIS will submit the September 2003 data with validation reports under separate cover. Analytical results are summarized in Tables 1 through 10.

Analytical Methodology

The samples summarized in the attached tables were submitted for analysis of dioxins and furans using one of two United States Environmental Protection Agency (U.S. EPA) analytical methods, summarized as follows:

- U.S. EPA Method 8290 Rev. 0 *"Polychlorinated Dibenzodioxins (PCDDs) and Polychlorinated Dibenzofurans (PCDFs) by High-Resolution Gas Chromatography/High-Resolution Mass Spectrometry (HRGC/HRMS)"* (September 1994).

- U.S. EPA Method 1613, Revision B *"Tetra- through Octa-Chlorinated Dioxins and Furans by Isotope Dilution HRGC/HRMS"* (October 1994).

All samples collected prior to calendar year 2003 were submitted to Triangle Laboratories, Inc. (Triangle), Durham, North Carolina and all analyses were conducted using U.S. EPA Method 8290. All subsequent samples were submitted to Severn Trent Laboratories, Inc. (STL), Knoxville, Tennessee and all analyses were conducted using U.S. EPA Method 1613B.

As indicated in the method titles, each method uses HRGC/HRMS. Each method is capable of detection and quantitative measurement of dioxins and furans at parts-per-trillion and parts-per-quadrillion concentrations. In addition, each method utilizes similar quality control criteria to identify a signal response (gas chromatographic peak) as a dioxin or furan congener. These quality control criteria were established to minimize the potential for misinterpretation of a peak yielded by matrix interference(s) to be a dioxin/furan congener. Matrix interferences may originate from laboratory contamination since solvents, reagents, glassware, and other sample processing hardware may yield artifacts and/or elevated baselines causing misinterpretation of chromatograms. Further, low level peaks that are close to the instrument detection limits can be significantly affected by instrument and chemical noise, and thus can lead to misinterpretation of chromatograms. The following table

provides the identification criteria and section where the identification criteria are presented for each of the methods. Both methods state that all of the listed criteria must be met for a signal response to be identified as a dioxin or furan congener.

Identification Criteria	U.S. EPA Method 8290	U.S. EPA Method 1613B
Retention Time	Sec. 7.8.4.1.1 through 7.8.4.1.3	Sec. 16.4
Mass-to-Charge Ratio	Sec. 7.8.4.1.4 through 7.8.4.1.5	Sec. 16.1
Ion Abundance Ratio	Sec. 7.8.4.2.1	Sec. 16.3
Signal-to-Noise Ratio	Sec. 7.8.4.3.1	Sec. 16.2
Polychlorinated diphenyl ether interferences	Sec. 7.8.4.4.1	---
Confirmatory analysis for 2,3,7,8-TCDD	---	Sec. 16.5

As indicated above, the methods have similar identification criteria. However, the major differences between the two methods are summarized below:

- The methods have different reporting requirements for a signal response (or peak) that does not meet all the identification criteria. U.S. EPA Method 8290 specifies that the peaks that meet the retention time criteria and signal-to-noise criteria be reported as an Estimated Maximum Possible Concentration (EMPC) value and flagged as such (Sec. 7.9.5.2.1). U.S. EPA Method 1613B specifies that values below the minimum level be reported as not detected or as required by the regulatory authority (Sec. 17.6.1.4.1).

- U.S. EPA Method 1613B specifies that if all the identification criteria are not met, the dioxin or furan congener has not been identified and the results may not be reported for regulatory compliance purposes (Sec. 16.6).

- U.S. EPA Method 1613B is approved under section 304(h) of the Clean Water Act for analysis of dioxins/furans, whereas U.S. EPA Method 8290 is not since it is a solid waste methodology. It should be noted that U.S. EPA Method 613, which is much less sensitive than U.S. EPA Methods 8290 and 1613B, is the only method currently approved under Part 31 of the Natural Resource and Environmental Protection Act (NREPA) for analysis of dioxins/furans. Michigan's proposed Part 31 rules would substitute U.S. EPA Method 1613B for U.S. EPA Method 613. U.S. Method 8290 is not the specified method.

- Pursuant to U.S. EPA's Fact Sheet, Method 1613B's use of isotope dilution techniques, internal standard calibration, and the 1600 series method quality control protocol, results in improved sensitivity, precision, and accuracy (http://www.epa.gov/waterscience/methods/1613.html).

The first point illustrates an important distinction between the two methods. U.S. EPA Method 8290, by reporting questionable peaks as an EMPC, creates ambiguity that can lead to misinterpretation of the data. From a technical perspective, reporting values from questionable peaks as an EMPC or as an elevated detection limit are equivalent (e.g., the intended chemistry behind each method is that dioxins/furans were not identified by the method, but could potentially be present below the level of the interferant). However, to persons without a background in analytical chemistry, a flagged EMPC can easily and erroneously be interpreted to mean that dioxins/furans are present in the sample since the data is reported as a discrete concentration and laboratory flags are not easy to find or understand for the uninitiated. U.S. EPA Method 1613B unambiguously states that these data cannot be used for regulatory compliance purposes.

The remaining points listed above further indicate that U.S. EPA Method 1613B for analysis of dioxins/furans in samples collected from groundwater along the Menominee River, pretreatment system influent/effluent, and IM/K WWTP influent/effluent provide the most valid data for use in MDEQ's evaluations relative to their NPDES program (ignoring the fact, for the moment, that Method 613 is the current Part 31 method).

Data Validation

As discussed in previous submittals to the MDEQ, ARCADIS does not consider the data generated by Triangle to be representative of Site conditions for the following reasons:

- Abundant matrix interferences (e.g., instrument signal noise, laboratory contaminants, etc.) for nearly all dioxin and furan congeners are present in the laboratory method blanks

- U.S. EPA Method 8290 is not approved for analyses of dioxins/furans under the Clean Water Act (CWA) or Part 31 of NREPA.

- At least one sample failed to meet quality control criteria and had to be rejected as invalid.

- Internal standard recoveries were routinely at the lower end of the acceptable range specified in the method.

- U.S. EPA Method 8290 specifies that for a gas chromatographic peak to be identified as a dioxin or furan, it must meet all of the identification criteria (Sec. 7.8.4).

It is the professional opinion of ARCADIS' data validation experts that Triangle's matrix interferences are more prevalent than what is typically encountered or acceptable for the evaluation of an analyte at concentrations between the practical quantitation limit (concentration of the lowest standard) and the method detection limit of the instrument. As a result, the Triangle data is suspect. Therefore, the switch to STL was implemented during calendar year 2003 (STL is qualified to perform analysis of dioxins/furans using U.S. EPA Method 1613B). STL has demonstrated excellent quality control with fewer instances of matrix interferences. The results of the dioxin and furan analyses by STL indicate that there are no detectable concentration of dioxins or furans in the Phase II Groundwater Pretreatment System effluent, in the groundwater pumped from the extraction wells, or in the five groundwater monitoring wells included in the September 2003 sampling program. Based on the STL data, all toxicity equivalence concentrations results have been zero and detection limits are well below U.S. EPA and MDEQ Target Detection Limits, Quantification Limits, and Minimum Levels.

Conclusions

In summary:

- It is ARCADIS' opinion that data generated by Triangle are not representative of site conditions due to quality control problems including abundant matrix interferences and at least on rejected data set. In addition, all Triangle data were generated using U.S. EPA Method 8290.

- Data generated by STL exhibits excellent quality control with fewer instances of matrix interferences. Further STL conducted their analyses of dioxins/furans using U.S. EPA Method 1613B, thus the data is in compliance with the analytical requirements of the CWA

- U.S. EPA Method 8290 is not approved under the CWA, Part 31 of the NREPA, or the proposed Part 31 rules.

For the reasons described above, ARCADIS recommends that all data generated using U.S. EPA Method 8290 be excluded from consideration by the MDEQ. The Triangle data are not valid for any further determinations by the MDEQ relative to monitoring requirements or discharge limitations in NPDES permits reissued to the IM/K WWTP or issued for the proposed full-scale groundwater treatment system. ARCADIS recommends that any additional sampling and analysis program include submission of samples to STL and Alta Analytical using U.S. EPA Method 1613B.

Closing

We appreciate MDEQ's cooperation on this issue. If you have any questions regarding this submittal or require any further information, please contact either of the undersigned.

Sincerely,

ARCADIS G&M, Inc.

All results reported as parts per quadrillion (picograms per liter)

D	Laboratory Filtered Sample
T	Unfiltered Sample
WWTP	Waste Water Treatment Plant
Triangle	Triangle Labs, Inc., Durham, North Carolina
STL	Severn Trent Laboratories, Inc., Knoxville, Tennessee
TEC_{dioxin}	Toxicity equivalence concentration of 2,3,7,8-TCDD for dioxins congeners.
TEC_{total}	Toxicity equivalence concentration of 2,3,7,8-TCDD for furans congeners.
TEC_{total}	Toxicity equivalence concentration of 2,3,7,8-TCDD for dioxins and furans congeners.

Notes:

(1) A concentration value of zero shall be used in the TEC calculation for any congener which is not present at or above its respective quantification level. The permittee shall report all analytical results that show the presence of any of the seventeen dioxin/furan congeners at levels that are at or above respective detection levels but less than the respective quantification levels.

BEF Bioaccumulation equivalency factor [MDEQ, Rule 323.1209(4)(ii)].
DL Detection limit.
ppq Parts per quadrillion (picograms per liter).
NA Information is not available.
ND Congener was not detected; contribution to the TEC is zero.
(ND) Detected result (as the shown concentration) was qualified as "not detected" due to associated blank contamination.
QL Congener quantifical limit for that sample.
TEC Toxicity equivalence concentration of 2,3,7,8-TCDD.
TEF Toxicity equivalency factor [MDEQ, Rule 323.1209(4)(ii)].

* TEC (ppq) = Detected result (ppq) × BEF × TEF

Data Qualifiers:
B – Compound was detected in the associated QC method blank sample.
E – Estimated maximum possible concentration.
J – Concentration is qualified as estimated.
X – Indicates a furan peak which exhibited interference from a diphnenyl ether peak of at least 10 percent of the total peak intensity.

(ND) Detected result was qualified as "not detected" due to associated blank contamination; contribution to the TEC is zero.

BEF Bioaccumulation equivalency factor [MDEQ, Rule 323.1209(4)(ii)].

DL Detection limit.

ppq Parts per quadrillion (picograms per liter).

NA Information is not available.

ND Congener was not detected; contribution to the TEC is zero.

QL Congener quantifical limit for that sample.

TEC Toxicity equivalence concentration of 2,3,7,8-TCDD.

TEF Toxicity equivalency factor [MDEQ, Rule 323.1209(4)(ii)].

* TEC (ppq) = Detected result (ppq) × BEF × TEF

Data Qualifiers:

B – Compound was detected in the associated QC method blank sample.

Q – Estimated maximum possible concentration.

J – Concentration is qualified as estimated.

U – Result was qualified as "not detected" during data validation.

(ND) Detected result was qualified as "not detected" due to associated blank contamination; contribution to the TEC is zero.

BEF Bioaccumulation equivalency factor [MDEQ, Rule 323.1209(4)(ii)].

DL Detection limit.

ppq Parts per quadrillion (picograms per liter).

NA Information is not available.

ND Congener was not detected; contribution to the TEC is zero.

QL Congener quantifical limit for that sample.

TEC Toxicity equivalence concentration of 2,3,7,8-TCDD.

TEF Toxicity equivalency factor [MDEQ, Rule 323.1209(4)(ii)].

* TEC (ppq) = Detected result (ppq) × BEF × TEF

Data Qualifiers:

B – Compound was detected in the associated QC method blank sample.

E – Estimated maximum possible concentration.

J – Concentration is qualified as estimated.

U – Result was qualified as "not detected" during data validation.

(ND) Detected result was qualified as "not detected" due to associated blank contamination; contribution to the TEC is zero.

BEF Bioaccumulation equivalency factor [MDEQ, Rule 323.1209(4)(ii)].

DL Detection limit.

ppq Parts per quadrillion (picograms per liter).

NA Information is not available.

ND Congener was not detected; contribution to the TEC is zero.

QL Congener quantifical limit for that sample.

TEC Toxicity equivalence concentration of 2,3,7,8-TCDD.

TEF Toxicity equivalency factor [MDEQ, Rule 323.1209(4)(ii)].

* TEC (ppq) = Detected result (ppq) × BEF × TEF

Data Qualifiers:

B – Compound was detected in the associated QC method blank sample.

Q – Estimated maximum possible concentration.

J – Concentration is qualified as estimated.

U – Result was qualified as "not detected" during data validation.

(ND) Detected result was qualified as "not detected" due to associated blank contamination; contribution to the TEC is zero.

BEF Bioaccumulation equivalency factor [MDEQ, Rule 323.1209(4)(ii)].

DL Detection limit.

ppq Parts per quadrillion (picograms per liter).

NA Information is not available.

ND Congener was not detected; contribution to the TEC is zero.

QL Congener quantifical limit for that sample.

TEC Toxicity equivalence concentration of 2,3,7,8-TCDD.

TEF Toxicity equivalency factor [MDEQ, Rule 323.1209(4)(ii)].

* TEC (ppq) = Detected result (ppq) × BEF × TEF

Data Qualifiers:

B – Compound was detected in the associated QC method blank sample.

E – Estimated maximum possible concentration.

J – Concentration is qualified as estimated.

K – Concentration exceeds the calibration curve; qualified as estimated.

R – Result was rejected during data validation.

U – Result was qualified as "not detected" during data validation.

Chicago, Illinois 60638

Dear Mr. Miller and Mr. Musgrove:

SUBJECT: Work Plan for Additional Dioxin/Furan Monitoring,
Full-Scale Groundwater Treatment System, and
NPDES Permit Application
Kingsford/Breitung Township Site, Kingsford, Michigan

We are writing in response to your Work Plan of January 22, 2004, regarding the additional dioxin/furan monitoring for the Kingsford/Breitung Township Site. The Michigan Department of Environmental Quality (MDEQ) Water Division (WD) and the Remediation and Redevelopment Division (RRD) are working together to review this plan in a timely manner. Consequently, we are providing our comments that are available at this time to advance the preparation of the Work Plan.

Your consultant, ARCADIS, has already received some preliminary verbal comments from the WD regarding the January submittal, which was subsequently slightly modified via a February 13, 2004 plan revision submittal. At this time, we are providing the MDEQ's initial comments on the introduction, background, sampling methodology, and well specification portions of the January 22, 2004 Work Plan. Because the content of the plan we are commenting on is essentially unchanged in the February 13, 2004 draft, the scope of this letter generally does not address the February 13, 2004 plan. However, we have determined that it is appropriate to include one comment on a paragraph in the February 13, 2004 plan revision. Additional comments that deal with the laboratory analytical Standard Operating Procedures, laboratory Quality Assurance and performance issues, and data reporting/review will be presented in a separate letter in the near future.

Section 1: Introduction

- The term "dioxin" should be defined early in the document as to what it applies to. The document uses *"dioxin," "dioxin and furans," "dioxin/furans,"* etc., and it would be better to use one global term in the document.

- Page 1/13, 1.0 Introduction, paragraph 1, sentences 2 & 3 of the Work Plan should be written as: "Initially ARCADIS constructed a Phase I pretreatment system consisting of a degasification/precipitation tank, an aeration blower, and a de-foaming system with the treated effluent being discharged to the sanitary sewer system serving the IM/K WWTP. In October 2001 construction of the Phase II pretreatment system was completed and the new system was put into operation which consisted of 2-fixed film bioreactors, associated aeration blowers, nutrient feed systems and piping, and a clarifier. In 2003, the Phase II system was re-designed to an activated sludge treatment process with associated aeration blowers, nutrient feed system and piping, a clarifier, and a liquid sludge storage

not correct completed

tank. Treated effluent from the Phase II System is currently being discharged to the sanitary sewer system serving the IM/K WWTP"

Section 2: Project Background

Section 2.0 is incomplete, contains inaccuracies, and misleads the reader, as written. The MDEQ does not consider this section necessary for inclusion in the Work Plan; however, in the February 4, 2004 conference call with the WD, ARCADIS stated their belief that this section must be retained. As the MDEQ finds it serves no pertinent purpose and increases the potential for misleading the reader, the MDEQ strongly disagrees with inclusion of this section. If FORD and KPC insist in retaining Section 2.0 in their Work Plan, then the MDEQ expects that the next revision will be complete and accurate, and the MDEQ points out the following inaccuracies and incomplete statements, for the record:

- Page 3/13, 2.1 FORD/Kingsford Site Background, sentence 2 of the Work Plan would have been more accurately written as: "The remaining liquid fraction, predominantly water and organic acids, with . . ."

- Page 3/13, 2.1 FORD/Kingsford Site Background, bullet 1 of the Work Plan states: *"No chlorinated chemicals were used in any of the processes."* This statement is contradictory to the data collected during the Remedial Investigation which found trichloroethene (TCE) present in the waste materials from the NE Pit in concentrations ranging up to 110,000 parts per billion (ppb).

  Bullet 2, of the Work Plan states: *"The pyrolysis process by which charcoal is generated and the distillation process are not combustion processes."* This is true, however, the burning of fuels such as excess charcoal, non-condensable gas, distilled wood tars and creosote oil, along with sawdust and shaving by-products in the Powerhouse, as specified in Section 2.1 of the Work Plan, is a potential source for dioxin/furan generation. The Work Plan fails to include this information. Also, the summary does not include discussion of the operation of the incinerator, or the waste products from the incinerator which was located at the SW Pit, as potential sources.

  Bullet 3, of the Work Plan, states: *". . . the wastes were land applied . . ."* This choice of words leads the reader to believe the wastes were disposed of in a well thought out manner. The wastes certainly were not "land applied" in the contemporary sense. In fact, the waste products generated by FORD/KPC plant operations were simply dumped in glacial kettles (e.g., pits). These pits were unlined, unlicensed, and extended to within five feet of the "current" static water levels at the site. At the time of disposal, the pits would have provided recharge to the underlying groundwater, where direct interactions between the waste liquids and groundwater would have occurred. This information is not included in the section.

  Bullet 5, of the Work Plan states: *"The waste disposal areas that are the sources of the subject groundwater plume are located a minimum of 3,000 feet from the Menominee River."* It is also evident that there is a large reservoir of contamination still present in the saturated zone that is also acting as a source of the subject groundwater plume. This observation is missing from the section.

- Page 4/13, 2.2.1: The second bullet is incomplete and does not note that the Michigan Water Quality Standards (WQS) also regulate the 2,3,7,8-TCDD congener on a congener specific basis.

- Page 4/13, 2.2 Sources of Dioxin/Furans, sentence 1 of the Work Plan states: *"Dioxins are ubiquitous in the environment and are present at parts per quadrillion and parts per trillion levels."* However, the U.S. Department of Health and Human Services

Toxicological Profile for Chlorinated Dibenzo-p-Dioxins, dated December 1998 strongly suggests that the generation of dioxin/furan is most commonly associated with anthropogenic sources (e.g., produced from industrial processes), rather than natural processes. This concept is lacking in Section 2. Additionally, the Section 2 discussion fails to note that dioxin/furan concentrations and congener fingerprints in contamination from industrial sources can be different from that resulting from natural sources.

- Page 5/13, 2.2.2 Sources of Dioxins/Furans, Bullet 5 of the Work Plan states: *"Production and recycling of certain metals."* Further clarification as to which metals this point addresses is lacking.

- Page 6/13, 2.2.3 Fate and Transport of Dioxins/Furans: Although the toxicological profile for dioxin (U.S. Department of Health and Human Services, 1998) indicates that dioxins generally will strongly adsorb to organic matter and are unlikely to leach to groundwater, the profile also goes on to indicate that dioxins may dissolve in other organic pollutants, making them more mobile through soil. As a general point, dioxin contamination of ground water has been documented at other sites of contamination in the United States. This information is lacking in Section 2. Regarding the presentation and discussion of the conventional wastewater treatment process proposed, Section 2.2.3 variously states that the proposed treatment: *"adequately prevents releases," "has been demonstrated to be successful in removing dioxins and furans,"* and *"are expected to appropriately address and prevent releases of dioxins and furans."* These descriptions appear to only acknowledge that conventional treatment can be capable of reducing dioxins/furans to levels below quantification, and sometimes below detection levels. This presentation fails to acknowledge that this level of control by itself is inadequate to clearly demonstrate that the waste stream is treated to a degree that complies with the requirements of the WQS.

- Page 6/13, 2.2.3 Fate and Transport of Dioxins/Furans, Bullet 1 of the Work Plan states: *"The absence of chlorinated materials (in other than relatively minor amounts) in the source area at the Site eliminates a potential source of dioxins/furans (e.g., disposal of polychlorinated biphenyls, chlorinated benzenes, chlorinated pesticides, etc.)."* Refer to the previous comment regarding TCE concentrations in the source materials.

  Bullet 3, of the Work Plan states: *"None of the sources of dioxin/furan listed in the previous section are related to historical operations at the site that resulted in wastewater discharge into the pits."* This statement does not reflect the fact that other potential sources of dioxins (e.g., fuels burned, the incinerator, waste materials from the powerhouse and incinerator, etc.) existed at the site. See the comments above regarding Bullet 2 of the Work Plan. Your analysis fails to include these obvious potential sources from your historical operations.

  This section should have included a description of all the other activities that occurred at this site, including the production of various chemicals.

  Bullet 4, the wording in sentence 2 of the Work Plan is incorrect (regarding consolidated soils). "Consolidated" refers to firm units (e.g., sand to sandstone); and drift deposits are normally referred to as unconsolidated deposits, not consolidated. The second part of the same sentence states: *". . . (including perched sand seams with little or no connectivity between other preferred pathways)."* This statement appears contradictory to the data gathered during the RI investigation because if there was little to no connectivity between other preferred pathways there would be little to no contamination in the Zone A, B, C, D sands.

Section 3: Sampling Plans

These Section 3 comments are not comprehensive as the MDEQ review of this section's discussion of analytical/SOP/ performance, etc., issues is not yet complete.

- Page 7/13, 3.1.1 Groundwater, Bullet 1, Shallow Wells Away from the Menominee River: replace monitoring well GM-62A with monitoring well GM-72.

  Bullet 2, Deep Wells Away from the Menominee River: include monitoring well GM-62C. Also monitoring well GM-5 should be included here.

  Bullet 3, Shallow Wells Along the Menominee River: replace monitoring wells GM-63A, and GM-66A with monitoring wells GM-25A, GM-26A, and GM-27A.

  Bullet 4, Deep Wells Along the Menominee River: replace monitoring well GM-25C, with monitoring well GM-64B.

- The plan must be changed in all the appropriate places to reflect the noted changes in the sampling wells.

Page 7/13, 3.1.2 Pretreatment System Influent (Groundwater Extraction Wells). Extraction Well GMEW-6 is not included in the discussion list of extraction wells to be sampled, but is included on Table D-1. The new river wells (GMEW 5-9) shall be sampled three times).

- Page 7/13, 3.1.2 Pretreatment System Effluent: The effluent samples should be collected with consideration of the site treatment plant detention time such that the effluent samples correspond with the information generated from the contemporaneous well samples.

- Page 8/13, 3.1.4 Split Samples. Split samples will provide an additional level of quality control, but the section shall be revised to address the following items:

Page 9/13, 3.3 Sampling Procedures, paragraph 3. New tubing must be used with the displacement pump for each well sampling event. This section must be expanded to discuss when, how, how many, etc., field and equipment blanks will be collected. Well sampling must also include collection and analyses of samples for other selected signature chemicals (such as the phenol compounds, BOD, etc.) in addition to the proposed physical measurements to provide necessary sample characterization. Because of the potential for cross contamination, we do not support placing probes in the well casing. This sampling procedure must have text added to define steps sufficient to ensure sample integrity and proper custody. Additional comments may be forthcoming on this part of the plan.

- Paragraph 4, sentence two of the Work Plan should be written as: "Oversight of all sampling activities will be conducted by the MDEQ or their subcontractor, if the MDEQ elects to do so."

- Page 10/13, 3.4 Sampling Schedule. Two sampling events are proposed: one during the first week in February 2004 and the second during the first week of March 2004. Since seasonal variations in dioxin/furan concentrations are a concern, the second sampling shall be conducted during the Spring (late April or early May 2004), and a third sampling event shall be included during the Summer (late July 2004).

- Page 10/14 (comment on 2/13/04 draft), 3.4, Sampling Schedule: The early sampling dates in this section obviously will need to be changed eventually to reflect the timeline of this submittal and review process. The data validation timeline comment in the first

paragraph should be deleted. The second paragraph notes that the "away" wells sampling plan are not included in this plan. However, it is mandatory that this plan include the "away" well sampling specifics as they are part of the site characterization that this plan is to achieve. Although the data from these wells may not be available in time for the permit development, the data will be relevant to permit conditions likely to be included in the permit. Consequently, the "away" wells must be part of this overall plan for generating a database for permit development and also for consideration of potential permit triggers.

Please incorporate these changes into the draft Work Plan. However, do not submit a revised Work Plan for MDEQ review until after you have received the additional MDEQ comments relating to analytical, performance, data reporting and data review, etc., aspects contained in Sections 3, 4, and 5 of the draft plan. We are currently working on compiling and discussing these additional comments. However, at this point we can state that inclusion of Figure D-3 as drafted is unacceptable.

Please contact Mr. Steven Casey at 906-346-8535 or Mr. Christopher Austin at 906-875-2072 if you have any questions about the above comments.

Sincerely,

Clifton Clark

Mr. Gary Lessard
Iron Mountain-Kingsford WWTP
P.O. Box 88
Kingsford, MI 49802

Dear Mr. Lessard:

SUBJECT: Suspended deadlines

The Michigan Department of Environmental Quality (MDEQ) is suspending the schedule for review of the monitoring plan to sample and analyze Ford/Kingsford site groundwater for dioxin and furans (Plan) and Sample Operating Procedures (SOPs) from the letter dated 2/18/04. MDEQ is continuing approval for the Iron Mountain-Kingsford Joint Sewage Board to continue its acceptance of flows from the Ford/Kingsford Phase II flows.

The MDEQ has numerous staff in different divisions of MDEQ, as well as Weston Solutions Inc., which are engaged in reviewing the Plan and SOPs. MDEQ is engaged with Arcadis when the Plan or SOPs they are reviewing is incomplete. This is accomplished via written and verbal notification of Arcadis to submit the necessary information. Arcadis submittals are necessary for MDEQ to provide technical comments on a complete Plan. Time is also necessary for the consolidation and discussion of MDEQ and Weston comments in order to provide formal comments to Arcadis. The MDEQ will continue to notify you of progress and the arrangement of deadlines for Plan approval and its initiation by Arcadis.

Thank you for your continued cooperation. Please contact me at (906) 346-8528 with any questions, concerns or comments.

Sincerely,

Ben Thierry

Dear Mr. Miller and Mr. Musgrove:

SUBJECT: Work Plan for Additional Dioxin/Furan Monitoring, Full-Scale Groundwater Treatment System, National Pollution Discharge Elimination System (NPDES) Permit Application, Kingsford/Breitung Township Site, Kingsford, Michigan

This letter provides additional Michigan Department of Environmental Quality (MDEQ) comments on the dioxin/furan (hereafter called dioxin) characterization work plan (WP) submitted as Attachment D of the NPDES permit application for the Kingsford/Breitung Township Site (hereafter the F/K Site). Two drafts of the WP have been submitted and these comments address both drafts. The comments below address WP sections 3.0, 4.0, and 5.0 which cover, in part, the analytical requirements, the data review/reporting requirements, and the data interpretation parts of the site characterization effort. Some initial WP comments were previously provided in the March 9, 2004, letter signed by us. A few additional comments were provided to Mr. Jon Forbort of Arcadis via a March 22, 2004, e-mail from Mr. Bruce Walker (MDEQ, Water Division). The WP must be revised to include the comments below as well as the previously transmitted comments. The revised WP should be submitted after Ford Motor Company and Kingsford Products Company (FORD/KPC) has received all MDEQ comments.

Although some comments below relate to the analytical aspects (i.e. SOP type issues) of the plan, we are not able to complete our review of all SOP related issues. An outstanding issue is that the ALTA analytical SOPs reviewed to date do not specify what kind of corrective actions are to be taken in response to some analytical or procedural issues that indicate something is out of compliance with QA/QC boundaries. Implementation of corrective actions to yield acceptable results must be a key part of the WP. The MDEQ must be provided with this type of information as part of the plan review/approval. Additionally, as noted below, there is yet much to be provided regarding the performance evaluation (PE) component of this plan as noted in the March 22, 2004, e-mail. Consequently, the MDEQ will be providing additional comments on these two issues in a subsequent letter.

Section 3.0 – Sampling Plan, Analytical Laboratories

1.) The final WP must specify collection of sufficient sample volume for each laboratory such that there is enough sample or extract volume to conduct a re-analyses if there are QA related problems with the initial sample analyses. With the small sample size being generated per

sampling point in this plan, it will not be acceptable to the MDEQ if analytical results for sampling points are lost or compromised due to sampling or analytical problems.

3) The final WP must specify that ultra clean, dioxin free sample bottles will be used and that dioxin free water will be used in any field blanks. Additionally, the proposed decontamination reagents/cleaning agents must be of similar grade and the decontamination process must be sufficient to prevent any potential cross contamination from sampling equipment that is reused.

4) The final WP must delete descriptors such as "primary" and "secondary" when discussing the proposed analytical laboratories. An objective of this effort is to obtain valid data from two laboratories and the MDEQ will consider the data of each approved laboratory to be of equivalent quality.

5) The final WP must include a complete description of the analytical and reporting directives/instructions that will be provided to the laboratories conducting the analyses.

6) The final WP must specify that samples within analytical runs that have associated QA/QC issues (excessive blank contamination, poor recoveries, atypically high detection levels, etc) that compromise the integrity or utility of the result(s) will be re-extracted, cleaned up, re-run after instrument cleanup or whatever is necessary (i.e. corrective actions) to produce acceptable results. Excessive blank contamination is detection of congeners at concentrations that are out of control relative to the laboratory's historic blank analyses. The statement in the draft plan that the reprocessing/re-analysis of a sample will occur only if there are problems that "... preclude identification at a level above the PQLs." must be deleted as it is unacceptable and is inconsistent with the objectives of the WP.

7) The final WP must state, for the wells selected for the plan objective of addressing the F/K site discharge to the Iron Mountain-Kingsford WWTP (IMK) facility that confirmed detection of dioxin (congener or TEC) above Michigan Water Quality Standards (WQS) in the initial samples can be a basis for termination of this WP's entire sampling program. The final WP also must state, for the wells selected for the plan objective of addressing the full-scale site treatment that confirmed detection of dioxin above WQS in those samples can be a basis for the termination of the remainder of that objective's sampling effort. Finally, the final WP must state that confirmed detection of dioxin in the site treatment plant effluent above WQS can also be a basis to terminate this plan's entire sampling program.

8) The final WP must include a complete section on the PE sample component of the plan. At the time of this letter, the PE component of the plan is incomplete. The performance sample shall include congener spike concentrations in the vicinity of the laboratories typical detection levels and some concentrations between the detection level and the EPA method 1613 specified MLs. The draft plan statement of setting spiking levels as close to the quantification level as possible must be deleted as it is unacceptable and is contradictory to the intent of this sampling program. The PE sample component must include details on corrective actions that will be triggered to address and correct unsatisfactory PE sample analyses as well as any site sample analyses associated with that PE sample.

Section 4.0 – Data Validation and Report Specifications

This section must be substantially changed as identified below through deletion of unnecessary proposed actions and clarification of some processes.

Data Validation

1) The final WP must delete all the draft plan references to and discussion about having data validated by Arcadis "experts".

2) The final WP must delete all the draft plan references to and discussion about data validation guidelines, references, or criteria other than those specified in EPA Method 1613 or those allowed by MDEQ (e.g. EMPC as previously discussed).

3) The final WP must delete all the draft plan references to and discussion about having the data "adjusted" (such as baseline adjustments, 5x the blank thresholds, recovery based corrections, etc) by Arcadis "experts".

4) The final WP must delete all references to and the presentation of the data review as noted in Figure D.3 because the draft work plan Figure D.3, as previously noted, is unacceptable to the MDEQ.

Data Reporting Specifications

1) The final WP must specify that a summary of the QA/QC acceptance criteria used by each laboratory will be included in each sample report.

2) The final WP must specify that each laboratory will report the sample congener results on both a quantified, if present at such a level, and detected basis. If a sample result requires coding which reflects an analytical issue, codes will be assigned to the respective result only by the appropriate laboratory analyst, not by FORD/KPC or Arcadis staff. All codes must be defined and any result that is determined by the laboratory to be unacceptable must be explained.

3) The final WP must specify that the laboratory result reports shall include total dioxin results for each of the tetra – octa substituted homolog groups.

4) The final WP must specify that each original, complete analytical report package generated by each laboratory will be mailed simultaneously to the specified contacts in Water Division (WD) and Remediation and Redevelopment Division (RRD) of MDEQ and the designated FORD/KPC, and IMK facility contacts. The sampling, analyses, and reporting must be coordinated between the laboratories such that the reports from each lab will contain the results for the same set of samples.

5) The draft plan notes the STL reporting of "EMPC" coding of data. The final WP shall specify that both laboratories report detections (coded with EMPC) that meet at least the retention time and S/N criteria. For EMPC coded data, the laboratory reports shall include a description of which identification criteria were not satisfied.

Data Summary Tables

1) As noted in the draft WP, data summary tables of detected and quantified congeners shall be presented using the format of prior submittals for this site. Only codes assigned by the analytical laboratory can be included in the summary tables. Non-detect results shall be reported as "< X.Y pg/l" rather than as "ND". The analytical results for the method blank associated with each sample shall be included in the table as done in previous submittals. The results reported by each laboratory for a specific sample shall be presented in a paired fashion so that the both sets of results for a sample are directly comparable in the summary tables.

2) For the preparation of the summary tables, the final WP must state that the only potential data manipulation applied to the reported congeners results will be the subtraction of the respective method blank value. Only method blank values that are within control can be subtracted from a raw result. The tables should highlight (bolded, shaded cell, etc) any congener value that is modified by subtraction of the blank value. Values determined for field blanks shall be included in the tables but may not be subtracted from any sample result.

3) The final WP must state that TEC values for individual samples will be calculated using the TEF and BEF values and TEC calculation formula presented in Rule 1209 of the WQS and the raw data from the summary tables discussed above. The only exceptions to this stated TEC calculation are that : 1) results that are "< DL" and appropriately coded EMPC results will be treated as "0" in the calculation and; 2) congener values may be "corrected" via subtraction to reflect within bounds method blank values. Unless there is a quantified result for a congener, the TEC calculations shall be made using the detection level results for the congeners.

4) The results and findings of the site characterization work shall be presented in a report(s), with the analytical data being presented consistent with the final WP which will incorporate the comments above, submitted to the designated contacts for WD and RRD and the IMK facility. The report shall be structured so that it presents the results and findings as applicable to each of the study's dual objectives.

5) If FORD/KPC wishes to present an interpretation of the study data using their own data "validation" rules which may be different from than those noted above, FORD/KPC may elect to submit separately a report detailing their alternative review of the data generated in this study. While the MDEQ will consider all relevant information, Ford/KPC must recognize that the MDEQ is under no obligation to accept the alternate review or its conclusions. Additionally, since FORD/KPC will be allowed the option to submit a separate data report, the final WP must not include the last sentence (i.e. the "...reserves their position..." statement) of the fifth bullet of Section 4.3 in the February 13, 2004, draft WP.

Section 5.0 – Data Review and Interpretation Specifications

This section shall be expanded, as described below, to describe the data review process and include the decision factors that will be used by MDEQ.

1) The final WP shall contain the following paragraph:
"At a minimum, if a final WP has not been approved by the time of the NPDES issuance, the NPDES permit for the F/K site, and the IMK facility as appropriate, will include dioxin related conditions which are effective upon permit issuance. If the data generated by this study are not adequate to clearly demonstrate to the MDEQ that dioxins are not present in the groundwaters or that any dioxins present at the F/K site are not at concentrations above WQS, the MDEQ will include and/or trigger dioxin related conditions in the NPDES permit for the F/K site and also, as appropriate, will require dioxin monitoring by the IMK facility. If the WP specified data for addressing the dual objectives are not provided in a timely fashion due to sampling or laboratory performance problems (e.g. blank issues, PE samples, QA issues, etc.), the MDEQ is under no obligation to extend the sampling period and the MDEQ reserves the right to require and/or trigger dioxin monitoring in either or both the Ford/KPC and IMK permits."

2) The final WP must state that the regulatory interpretation of the data determined to be acceptable by the MDEQ will be based on the highest congener and/or TEC values from either or both laboratories. The purpose of this statement is to clarify that if there are differences between

laboratories in the analytical results for a sample, the MDEQ review must be conservative in nature and the review must use the higher result(s).

3) The final WP must state that the confirmed detection by either laboratory of dioxin congeners or a dioxin TEC above WQS in any individual well or site effluent sample at any time is sufficient basis to conclude that dioxins are present at levels of concern in the site groundwaters and that this finding provides a basis for including dioxin permit conditions in the Ford/KPC permit and, as appropriate, requiring dioxin monitoring by the IMK facility if they are accepting effluent or groundwaters from the F/K site.

4) Inclusion of the above comments eliminates the need for Figure D.4. However, if the final WP is to contain Figure D.4, it must be modified to correct a WQS value error (3.5 should be 3.1) and the text must be made consistent with the above comments. Additionally, we would prefer the WP document and figures use the units of "parts per quadrillion" rather than "parts per quintillion".

Please contact Mr. Ben Thierry at (906) 346-8528 if you have questions on the above comments.

Subject:
Attachment D, Work Plan for Additional Dioxin/Furan Monitoring, Full-Scale Groundwater Treatment System, National Pollutant Discharge Elimination System (NPDES) Permit Application, Ford/Kingsford Site, Kingsford, Michigan

---

The purpose of this memorandum is to establish a work plan to analyze groundwater at the subject site for polychlorinated dibenzo-p-dioxins and polychlorinated dibenzofurans (dioxins/furans), and to establish a consensus among the Michigan Department of Environmental Quality (MDEQ) Remediation and Redevelopment Division (RRD), the MDEQ Water Division (WD), the Iron Mountain/Kingsford Wastewater Treatment Plant (IM/K WWTP), Ford Motor Company, The Kingsford Products Company, and ARCADIS for the execution of the plan and specifications for reporting, congener identification, data review, and data interpretation.

The work plan presented herein is a support document for a NPDES permit application for the proposed full-scale treatment system designed for the ex-situ treatment of impacted groundwater and subsequent discharge of treated effluent to the Menominee River. The additional data are being generated to:

- Address MDEQ concerns with the potential for discharge of dioxins/furans from the existing pretreatment system to the IM/K WWTP, which will continue as long as practicable until the full-scale treatment system is operational.
- Address MDEQ concerns with the potential for the full-scale treatment system discharge to exceed Michigan Part 31 Rules discharge standards for dioxins/furans to the Menominee River.

1.0 Introduction

As a component of a multi-phase pilot program proposed in a draft work plan submitted to the MDEQ to address venting groundwater along the Menominee River (*"Work Plan for Investigation and Pilot Pumping Studies Along the Menominee River, May 30, 2000"*), a groundwater extraction and pretreatment

system was constructed in 2001. ARCADIS initially constructed a Phase I pretreatment system (Phase I System) consisting of a degasification/precipitation tank, an aeration blower, and a de-foaming system with the treated effluent being discharged to the sanitary sewer system serving the IM/K WWTP. In October 2001, construction of the Phase II pretreatment system (Phase II System) was completed and operation of the new system, consisting of two fixed-film bioreactors, associated aeration blowers, nutrient feed systems and piping, clarifier, and a liquid sludge storage tank was initiated. In 2003, the Phase II system was re-designed as an activated sludge treatment process with associated aeration blowers, nutrient feed system and piping, a clarifier, and a liquid sludge storage tank. Treated effluent from the Phase II System is currently being discharged to the sanitary sewer system serving the IM/K WWTP (historically, discharge flows have averaged less than 60 gallons per minute [gpm]). Based on the findings of the pilot testing, the conceptual design for the proposed full-scale groundwater treatment system was completed consisting of pretreatment aeration and clarification for metals removal, first-stage biological treatment using activated sludge aeration basins with gravity clarification, followed by second- stage biological treatment using submerged fixed-film bioreactors with gravity clarification. However, the pretreatment system will continue to operate (up to 100 gpm) and discharge treated effluent to the IM/K WWTP during construction of the full-scale system. ARCADIS anticipates that the pretreatment system will be shut down in summer 2005 to integrate the existing equipment into the full-scale treatment plant.

1.1 Existing Dioxin/Furan Data

Historical dioxin/furan data was generated using the following United States Environmental Protection Agency (U.S. EPA) Methods:

- U.S. EPA Method 8290, Revision 0 *"Polychlorinated Dibenzodioxins (PCDDs) and Polychlorinated Dibenzofurans (PCDFs) by High-Resolution Gas Chromatography/High-Resolution Mass Spectrometry (HRGC/HRMS)"* (September 1994).

- U.S. EPA Method 1613, Revision B *"Tetra- through Octa-Chlorinated Dioxins and Furans by Isotope Dilution HRGC/HRMS"* (October 1994).

U.S. EPA Method 1613, Revision B is approved under the Clean Water Act for analysis of dioxins/furans, whereas U.S. EPA Method 8290 is not. Since the majority of the historical data was generated by U.S. EPA Method 8290, the MDEQ has concluded that additional sampling and laboratory analytical data using U.S. EPA Method 1613B is required.

2.0 Sampling Plan

The sampling plan presented in this section specifies the sampling locations, number of sample rounds, procedures for collecting samples, a brief description of sampling methods, and a listing of the laboratories selected to perform the analyses. Sample locations relevant to the pretreatment system discharge to the IM/K WWTP include five monitoring wells along the Menominee River, the four extraction wells that are currently piped to the pretreatment system, and the pretreatment system effluent. Sample locations relevant to the full-scale groundwater treatment system include six monitoring wells located away from

the Menominee River and five future extraction wells in addition to the existing pretreatment system. Samples relevant only to the pretreatment system discharge will be designated as "Pretreatment." Samples not relevant to the pretreatment system will be designated as "Full-Scale" for purposes of clarity (the "Pretreatment" samples are also relevant for interpretation of the full-scale treatment system). It should be noted that the wells sampled under this plan are a representative subset of a larger network of both existing and future wells at the site, and provide a comprehensive and appropriate characterization of the site groundwater.

2.1 Sample Locations

In developing the basis for sampling locations, the following objectives were identified:

- Supplement existing Method 1613B dioxin and furan data for groundwater with samples from monitoring wells and extraction wells as described in Section 2.1.1 and 2.1.2 to determine the lateral and vertical extents of dioxins/furans, if any.
- Supplement existing Method 1613B dioxin and furan data for the pretreatment system influent (e.g., groundwater extraction wells as described in Section 2.1.2).
- Supplement existing Method 1613B dioxin and furan data for the pretreatment system effluent (as described in Section 2.1.3).

2.1.1 Groundwater Monitoring Wells

The following groundwater monitoring wells have been selected for sample collection:

- Shallow Wells Away from the Menominee River (Full-Scale): GM-37A, GM-72A
- Deep Wells Away from the Menominee River (Full-Scale): GM-37B, GM-62B, GM-62C, GM-5
- Shallow Wells Along the Menominee River (Pretreatment): GM-25A, GM-26A, GM-27A
- Deep Wells Along the Menominee River (Pretreatment): GM-26C, GM-64B (not yet re-installed)

Monitoring Wells GM-37A, GM-37B, GM-62B, GM-5, and GM-62C are located upgradient from the areas along the Menominee River, but are downgradient from the former pits. Monitoring Well GM-72A is located directly beneath the former Northeast Pit. Monitoring Wells GM-25A, GM-26A, GM-26C, GM-27A, and GM-64B are within the areas that will be subject to hydraulic control via extraction wells under the full-scale pumping scenario. The monitoring wells provide lateral and vertical coverage (Zones A, B, C, and D). Refer to Figure D-1 for a site plan with the locations of the monitoring wells, and to Figure D-2 for a cross-section of the area along the Menominee River.

2.1.2 Pretreatment System Influent (Groundwater Extraction Wells)

The following extraction wells will be analyzed:

- Pretreatment: GMEW-1, GMEW-2, GMEW-3, GMEW-4R
- Full-Scale: GMEW-5, GMEW-6, GMEW-7, GMEW-8, and GMEW-9

These wells will also be used to supplement the lateral and vertical coverage of the monitoring wells described in Section 2.1.1

2.1.3 Pretreatment System Effluent

Samples of the pretreatment system effluent will be collected and submitted for analysis of dioxins/furans. Samples will be collected with consideration of the pretreatment system detention time such that the effluent samples correspond with the information generated from the contemporaneous extraction well samples.

2.1.4 Split Samples

The purpose of split samples is to provide an additional level of quality control, and the split samples should be equivalent and thus provide a metric for comparing each laboratory's sample preparation and analytical capabilities (e.g., level of precision and accuracy). Split sample replicates will be collected concurrently at each sample location, and will be submitted to both laboratories presented in Section 2.2.

2.1.5 Equipment Blanks

The purpose of equipment blanks is to check for potential procedural contamination during sample collection activities that may be caused by deficiencies in decontamination procedures or new sampling equipment. For wells sampled using the bladder pump, the equipment blanks will be collected by rinsing the decontaminated sampling equipment and new tubing with distilled water (provided by the laboratory). For wells sampled with the peristaltic pump where the only sampling equipment that comes in contact with the groundwater is new tubing, the equipment blank will be collected by pouring distilled water (provided the laboratory) through the tubing. In each case, the rinsate will be collected for laboratory analysis. All equipment blanks will be collected at a frequency of one equipment blank for every ten samples. Enough sample volume will be collected such that replicate equipment blank samples can be submitted to both laboratories presented in Section 2.2.

2.1.6 Field Blanks

The purpose of field blank samples is to further assess the quality of data from the field sampling program Field blanks will be collected in the field by filling sampling containers with distilled water (provided by

the laboratory). Field blanks will be collected at a frequency of one for every ten samples, or at a minimum of one per day. Enough sample volume will be collected such that replicate field blank samples can be submitted to both laboratories presented in Section 2.2.

2.1.7 Temperature Blanks

Temperature blanks consisting of distilled water (provided by laboratory) will be submitted with each sample cooler shipped. Temperature blanks will be included so that the temperature of the samples can be measured if no ice is present in the shipment container. If the sample does not meet U.S EPA Method 1613B temperature specifications, ARCADIS will be notified by the laboratory project manager so that an informed decision can be made whether to proceed with analysis of the sample.

2.1.8 Additional Quality Assurance/Quality Control

Performance samples can be used to provide another level of quality assurance/quality control (e.g., sample prepared by an outside contractor with a known concentration of analyte submitted with the field samples). However, it is not currently possible to prepare a performance sample with a concentration between the instrument detection limit and the minimum level specified in Method 1613B since the minimum level (PQL) is the lowest point in the calibration curve for the instrument. In other words, a supplier of laboratory standards will not certify a performance sample below the PQL because it is below the calibrated range of the instrument. Therefore, in lieu of performance samples, MDEQ has requested that the laboratories demonstrate the quality of the data produced by analyzing a quality control (QC) check sample (as referenced in Sections 7.16 and 9.6 of U.S. EPA Method 1613B) immediately before the analyses of the samples from the first sampling round and third sampling round. This sample will be analyzed with any other QC samples (e.g. laboratory control sample) prior to the method blank and the samples submitted for analysis. To address contaminant carryover, it is standard procedure to run a rinse sample between the QC samples and the method blank. The analysis of the QC check sample will be requested on a chain-of-custody submitted during the first sample round and third sampling round.

2.2 Analytical Laboratories

Split samples will be submitted to both laboratories identified below for analysis of dioxins/furans using U.S. EPA Method 1613B in accordance within the schedule proposed in Section 2.4.

Severn Trent Laboratories, Inc.

Phone: (865) 291-3000
Laboratory Quality Manual, Revision 2, July 17, 2003

Alta Analytical Laboratory Inc.
1104 Windfield Way
El Dorado Hills, California 95762
Phone: (916) 933-1640
Laboratory Quality Manual, Revision 1.0, March 2003

Laboratory Quality Manuals (revision information listed above) for each of the laboratories have been submitted to the MDEQ RRD and WD divisions under separate cover. A summary of project analytical and reporting requirements to be provided to each laboratory is presented in Attachment A.

2.3 Sampling Procedures

The collection of groundwater samples for dioxin/furan analysis will be conducted in accordance with the procedures described in the RI Report for the Ford/Kingsford site (ARCADIS, June 2002). The groundwater samples will be collected from the monitoring wells using low-flow purging and sampling techniques. An air-piston positive displacement pump (Model 1800), a bladder pump (Model R8550021D), or a peristaltic pump (Model L/S 7570-10) will be used to complete the low-flow purging and sampling. The piston or bladder pump will be used for deep groundwater wells and the peristaltic pump will be used for shallow groundwater wells. New tubing will be used with the bladder and peristaltic pumps for each sampling event. A decontaminated water level probe will be used to monitor the depth to water during sampling activities to demonstrate that the static water level is not affected by low-flow sampling. To minimize the potential for cross-contamination, a down-hole probe (e.g., YSI) will not be deployed to measure parameters during the sampling events; however, a flow-through cell will be used at the well head to monitor well parameters during sample collection.

In accordance with previous sampling results and procedures, sampling order will be from the well with the lowest historical concentrations of the site-specific target compound list (TCL) parameters (non-dioxin/furan constituents) to the well with the highest TCL concentrations (non-dioxin/furan constituents).

The monitoring wells will be purged at a flowrate between 100 and 500 milliliters per minute until the field parameters stabilize. The groundwater samples will be collected by filling the sample containers directly from the pump tubing at the stabilized purging flowrate. Samples will be collected in ultra clean, dioxin-free laboratory-supplied sample bottles. Upon collection, the groundwater samples will be placed on ice in a cooler and submitted under appropriate chain-of custody protocol to each of the selected laboratories. Three liters of groundwater will be collected at each sample location for each laboratory. That sample volume will insure that two or three analytical runs can be performed per sample, if needed.

Any sampling equipment not dedicated to a monitoring well will be decontaminated with detergent solution wash and de-ionized water, as well as a hexane rinse, prior to and between each sampling event. De-ionized water and hexane will be supplied by the laboratory and/or their subcontractor. Any decontaminated sampling equipment will be stored in aluminum foil to prevent contamination from plastics or other organic wrappings. New silicone and polyethylene tubing will be used with the peristaltic

pump for each sampling event and will be discarded following completion of the sampling. New, disposable latex gloves will be worn by the sampling personnel and discarded after each sampling event. The water extracted during the monitoring well purging and sampling activities will be contained in plastic buckets or steel drums and transported to the pretreatment system for appropriate treatment.

ARCADIS personnel will perform all the work associated with the sampling activities described herein. Oversight of all sampling activities will be conducted by the MDEQ or their subcontractor, if the MDEQ elects to do so.

2.4 Sampling Schedule

ARCADIS proposes the collection of two rounds of data for each of the sampling locations discussed in Section 2.1 above. The proposed schedule for the sampling is the collection of the first round during the first or second week of October 2004, and the collection of the second round during the first or second week of December 2004. A sample collection matrix and schedule is included in Table D-1. It is expected that analytical reports will be generated 6 to 7 weeks after samples are received at each laboratory.

In addition, one (1) additional round of samples from the monitoring wells away from the Menominee River (GM-37A, GM-72A, GM-37B, GM-62B, GM-62C, and GM-5) will be required to address MDEQ requirements for temporal sampling. This temporal sample event would be proposed for spring of 2005.

3.0 Data Review and Reporting Specifications

Data will be generated and reported by the laboratory per the requirements of U.S. EPA Method 1613B. The review of these data will be consistent with U.S. EPA Method 1613B and other congener identification review specifications detailed by the MDEQ in this work plan.

3.1 Congener Identification Criteria

Per Section 16.0 of U.S. EPA Method 1613B, all of the identification criteria must be met before a peak can be identified as a dioxin/furan congener (in a standard, blank, or sample). If any single identification criteria (or combination) is outside the acceptable range, the peak is **NOT** a dioxin/furan congener, and the analyte must be identified as a non-detect with a QC flag. Non-detects will be treated as zero in the subsequent toxicity equivalency concentrations (TEC) calculations. Congener identification criteria from U.S. EPA Method 1613B are as follows:

1. The signals for the two exact mass to charge ratios specified in Table 8 of U.S. EPA Method 1613B must be present and must maximize within the same two seconds.

2. The signal-to-noise ratio must be above 2.5 for all suspected dioxin/furan peaks.

3. Ion abundance ratios must be within the limits specified in Table 9 of U.S. EPA Method 1613B.

4. Relative retention times for 2,3,7,8-substituted chlorinated dibenzo-p-dioxin and chlorinated dibenzofuran must be within the limits specified in Table 2 of U.S EPA Method 1613B.

5. Confirmatory analysis must be performed for any peaks identified as 2,3,7,8-tetrachlorodibenzofuran using the gas chromatograph columns specified in U.S. EPA Method 1613B.

3.2 Laboratory Reporting Criteria

The project analytical and reporting requirements to be provided to each laboratory are presented in Attachment A; a brief summary is as follows. The laboratory will report data consistent with the requirements of U.S. EPA Method 1613B, which pursuant to Section 16.6, states the following:

- If the criteria for identification, summarized above, are not met, the dioxin or furan has not been identified. *"If interferences preclude identification, a new aliquot of sample must be extracted, further cleaned up, and analyzed."*

Each laboratory will run the samples in the sampling order and will report the "pretreatment" and "full-scale" samples in separate batches. In addition to the reporting requirements specified in U.S EPA Method 1613B, the laboratory will be required to report the method detection limit (it is a common practice for laboratories to exclude the method detection limit from the report when there is a reportable concentration). Only the laboratory will code the data. The laboratory reports will include chromatograms, all calibrations, and all raw quality control data (e.g., quantitation reports). A final copy of each laboratory report will be distributed by the laboratory to Ric Studebaker of ARCADIS and to Chris Austin and Gerry Saalfeld of MDEQ. In addition, the laboratory reports will be reported electronically as a portable document format and in electronic data deliverable.

3.3 Data Review Guidelines

The following definitions are provided to maintain consistent terminology for detection and quantitation limits:

- Detection Level: The minimum concentration of an analyte that can be measured above the instrument background noise. Also referred as instrument detection limit, detection limit, or estimated detection limit.

- Quantitation Level: The level at which the entire analytical system must give a recognizable signal and acceptable calibration point for the analyte. It is equivalent to the concentration of the lowest calibration standard. Also referred to as minimum level, or PQL.

The following data review actions are anticipated:

- Matrix interferences are sometimes observed in the method blanks. Per U.S. EPA Method 1613B, method blanks should be free from contamination or matrix interferences (e.g., there should be non-detects for all congeners). If excessive method blank contamination occurs, or if 2,3,7,8-TCDD is detected in a method blank, the samples associated with the method blank will be re-extracted, cleaned up, and re-run in accordance with U.S. EPA Method 1613B and each laboratory's corrective action procedures. Excessive blank contamination is defined to be detection of congeners at concentrations that are out of control relative to the laboratory's historic blank analyses.

- If unacceptable contamination (e.g., unusually high and/or numerous congeners) is found in the field or equipment blanks, samples with detections associated with the blanks will be disqualified as invalid data and will be resampled. Samples that are non-detect will be valid since these samples were not affected by potential field procedures.

3.3.1 Data Reports and Summary Tables

For each sampling round, ARCADIS will prepare a brief summary report that includes a cover letter, summary data tables, and summary analytical reports. If an analytical laboratory's preliminary results show the presence of detectable levels of dioxins/furans, the laboratory will immediately forward these data to ARCADIS. ARCADIS will notify the MDEQ of these preliminary findings within seven days. Summary tables will be prepared in the format submitted for all the existing sample data. Replicate samples will be paired to facilitate comparison of analytical results from each laboratory. Summary tables will also contain the following information:

- Bioaccumulation equivalency factors (BEF) will be provided in accordance with Part 8, Rule 1209, Table 2. BEF provides toxicological information on chlorinated dibenzo-p-dioxin and chlorinated dibenzo-p-furans relative to 2,3,7,8-tetrachlorodibenzo-p-dioxin.

- Toxicity equivalency factors (TEF) will also be provided in accordance with Part 8, Rule 1209, Table 2. TEF provides information on the toxicity associated with a mixture of chlorinated dibenzo-p-dioxins and chlorinated dibenzo-p-furans relative to the toxicity of 2,3,7,8-tetrachlorodibenzo-p-dioxin.

- Sample TECs will also be provided. In accordance with previous dioxin submittals, one table will summarize TEC calculation using data above the detection level and a second table will summarize TEC calculations using data above the MDEQ's target detection limit. In accordance with Part 8, Rule 1209, the BEF and TEF factors will be used to calculate the TEC for a sample. First, the TEC for a specific congener (TEC_i) will be calculated as follows (including subtracting out method blank concentrations associated with the samples, provided that excessive method blank contamination is not present as described in Section 3.3 above):

TEC_i = [(sample concentration) – (method blank concentration)] × TEF × BEF

Or

$TEC_i = 0.$

Second, the TEC for the sample will be calculated as follows:

$TEC=\sum TEC_i$

TEC calculations with method blank concentrations subtracted from an associated sample result will be identified with a shaded cell in the table.

- Detection levels, analytical results, and quantitation levels will also be provided in the summary tables.
- Non-detects will be reported as "<X.X" picograms per liter in lieu of "ND". Analytical results for the method blank associated with each sample will also be included (as in previous submittals).
- Data that has not met congener identification criteria will be reported as a non-detect with the laboratory specific data qualifying flag. Footnotes will be included with each of the tables with a description of each data qualifying flag.

ATTACHMENT A
Guidelines for Analysis and Reporting of Dioxin Samples Collected From the Ford/Kingsford Site.

Dioxin samples collected from the Ford/Kingsford site will be analyzed and reported according to the information contained within this memo. It is anticipated that there will be two sampling events each consisting of approximately 20 primary samples, five field blanks, and two equipment blanks. The proposed schedule for the sampling is the collection of the first round during the third or fourth week of October 2004, and the collection of the second round during the first or second week of December 2004. A third sampling round, consisting of approximately seven primary samples, three field blanks, and two equipment blanks, will be collected during 2005. Three liters of groundwater will be collected at each sample location to ensure that two or three analytical runs can be performed per sample, if needed.

The following information is provided to support the analysis of these samples:

1) Samples will be run by United States Environmental Protection Agency (U.S. EPA) Method 1613B.

2) Samples will be run in the sampling order, based on chain-of-custody sampling date and time. Samples will be held until all samples are received for each sampling event. Approximately 27 will be received by the laboratory for the first two sampling rounds and 12 samples for the third sampling round. A representative of ARCADIS will contact the laboratory to confirm that all samples have been received prior to sample extraction and analysis. All samples will be extracted at the same time and then run in two consecutive analytical batches.

3) Samples will be run for the 17 congeners listed on Table 1 of U.S. EPA Method 1613B. Totals will not be reported since these may include other dioxin/furans not listed on this table.

4) A low-level quality control (QC) check sample (as referenced in Sections 7.16 and 9.6 of U.S. EPA Method 1613B) will be analyzed immediately before the analysis of the samples from the first sampling round and the third sampling round (at a minimum). This sample will be analyzed with any other QC samples (e.g. laboratory control sample) prior to the method blank and the samples submitted for analysis. To address contaminant carryover, a rinse sample will be run between the QC samples and the method blank.

5) A second method blank will be run with each analytical batch (e.g., a total of four method blanks for each of the first two sampling events and a total of two method blanks for the third sampling event).

6) Congener Identification: Per Section 16.0 of U.S. EPA Method 1613B, all of the identification criteria must be met before a peak can be identified as a dioxin/furan congener (in a standard, blank, or sample). If any single identification criteria (or combination) is outside the acceptable range, the peak is not a dioxin/furan congener, and the analyte must be identified as a non-detect with a QC flag. Congener identification criteria from U.S. EPA Method 1613B are as follows:

a) The signals for the two exact mass to charge ratios (m/z) specified in Table 8 of U.S. EPA Method 1613B must be present and must maximize within the same two seconds.

b) The signal-to-noise ratio (S/N) must be above 2.5 for all suspected dioxin/furan peaks.

c) Ion abundance ratios must be within the limits specified in Table 9 of U.S. EPA Method 1613B.

d) Relative retention times for 2,3,7,8-substituted chlorinated dibenzo-p-dioxin and chlorinated dibenzofuran must be within the limits specified in Table 2 of U.S EPA Method 1613B.

e) Confirmatory analysis must be performed for any peaks identified as 2,3,7,8-tetrachlorodibenzofuran using the gas chromatograph columns specified in U.S. EPA Method 1613B.

Note: Peaks that meet the retention time **and** signal-to-noise criteria described above, but **do not** meet the remaining congener identification criteria will be reported as non-detect and the elevated detection limit flagged indicating that the "Does not meet all the method specified congener identification criteria."

The following information is provided to support the reporting of these samples:

1) The laboratory will group the "pretreatment" and "full-scale" samples in separate laboratory reports. The attached table (Table A-1) identifies the samples as "pretreatment" or "full-scale."

2) In addition to the reporting requirements specified in U.S EPA Method 1613B, the laboratory will be required to report the method detection limit (e.g., EDL).

3) If preliminary results show the presence of detectable levels of dioxins/furans, the laboratory will immediately forward these data to ARCADIS. ARCADIS will notify the MDEQ of these preliminary findings within seven days.

4) The laboratory reports will consist of a full data package and include: narrative explaining qualified (flagged) results, initial calibration (ICAL), continuing calibrations (CCALs), method blanks (MB), ongoing precision and recovery (OPR), sample raw data, confirmation data (if applicable), quality control and sample datasheets, sample preparation bench sheets, and receiving documents (e.g., chain of custody, sample receiving checklist, etc.).

5) A final copy of each laboratory report will be distributed by the laboratory to the following three individuals:

Ric Studebaker
ARCADIS
126 N. Jefferson Street Ste. 400
Milwaukee, Wisconsin 53202

Gerald Saalfeld
Water Division
Michigan Department of Environmental Quality
MDEQ-Water Division, 2 South
525 West Allegan
Lansing MI 48933

Chris Austin
Michigan Department of Environmental Quality
Remediation and Redevelopment Division
1420 West US Hwy. 2
Crystal Falls, MI 49920-9623

6) Each laboratory report will also be reported electronically as a portable document format (PDF) and in electronic data deliverable (EDD) format.

The following data review actions are anticipated:

- Matrix interferences are sometimes observed in the method blanks. Per U.S. EPA Method 1613B, method blanks should be free from contamination or matrix interferences (e.g., there should be non-detects for all congeners). If excessive method blank contamination occurs, or if 2,3,7,8-TCDD is detected in a method blank, the samples associated with the method blank will be re-extracted, cleaned up, and re-run in accordance with U.S. EPA Method 1613B and each laboratory's corrective action procedures. Excessive blank contamination is defined to be detection of congeners at concentrations that are out of control relative to the laboratory's historic blank analyses.

- If unacceptable contamination is found in the field or equipment blanks, samples with detections associated with the blanks will be disqualified as invalid data and will be resampled. Samples that are non-detect will be valid since these samples were not affected by potential field procedures.

Mr. Daniel Musgrove
The Kingsford Products Company
5064 South Merrimac Ave.
Chicago, Illinois 60638

Dear Mr. Miller and Mr. Musgrove:

SUBJECT: Work Plan for Additional Dioxin/Furan Monitoring, Full-Scale Groundwater Treatment System, National Pollution Discharge Elimination System (NPDES) Permit Application, Kingsford/Breitung Township Site, Kingsford, Michigan

This letter provides Ford Motor Company and Kingsford Products Company (FORD/KPC) with MDEQ comments upon and provisional approval of the dioxin/furan (hereafter called dioxin) characterization work plan (WP) submitted as Attachment D of the NPDES permit application for the Kingsford/Breitung Township Site (hereafter the F/K Site). A number of drafts of the WP previously have been submitted, reviewed and commented upon and the latest draft reflects recent discussions with FORD/KPC representatives (Arcadis), the analytical laboratories, and MDEQ staff via emails and telephone calls. The comments and approval contained in this letter are pertinent to the October 14, 2004, draft of the WP.

The MDEQ approves the October 14, 2004, WP contingent upon the incorporation of the comments and topics below into the understanding of and execution of the WP by Arcadis.

1) Section 1 of the October 14, 2004, draft of the WP references a May 30, 2000, draft work plan to address venting to the Menominee River. For the record, the MDEQ again states that the May 30, 2000, draft work plan to address venting to the Menominee River did not fulfill the objectives specified in the February 29, 2000, letter from the MDEQ to Ford/KPC. This shortcoming has been noted more than once by the MDEQ.

2) For purposes of clarification, the use of the term "full-scale" for the WP described groundwater sampling and plume characterization is considered to be specific to the execution of this WP since future "full-scale" operations at the site will encompass a different set of wells, monitoring efforts, and control actions.

3) As noted in a previous draft of the WP and as communicated to Arcadis, the MDEQ will review and interpret the data and findings generated by this WP largely based upon the data review and interpretation positions contained in Section 5.0 of the April 6, 2004, MDEQ letter from Mr. Casey and Mr. Clark to Ford/KPC.

4) The only modification and "coding" by Arcadis of the laboratory results summarized by Arcadis staff would be the potential subtraction of method blank values from the sample results

as previously communicated to Arcadis by MDEQ. It is the position of the MDEQ, and it is our understanding that Arcadis agrees, that it is inappropriate to subtract excessive method blank results from associated sample results. Consequently, the MDEQ reserves the right to interpret the analytical results independent of elevated or excessive method blank results. This position, however, does not preclude the subtraction of typical, low level method blank contamination from sample results.

5) To emphasize a significant point included in the MDEQ April 6, 2004, letter, we wish to restate that if the WP specified data for addressing the dual objectives of the WP are not provided to the MDEQ in a timely fashion due to sampling and/or laboratory performance problems (e.g. blank contamination issues, lab QA issues, etc.), the MDEQ is under no obligation to extend the sampling period and the MDEQ reserves the right to require and/or trigger dioxin monitoring in either or both the Ford/KPC and Iron Mountain/Kingsford WWTP (IMK) permits. Through Arcadis, Ford/KPC is responsible for ensuring that the sampling is conducted properly and promptly and that the desired data are generated in an acceptable manner. Additionally, if the data generated by this study (including the detection level data) do not clearly demonstrate to the MDEQ that dioxin concentrations in the groundwaters are less than Michigan Water Quality Standards, the MDEQ will include and/or trigger dioxin related conditions in the NPDES permit for the F/K site and also, as appropriate, will require dioxin monitoring by the IMK facility.

6) MDEQ approval of the WP does not mean that all data generated will be automatically considered acceptable by the MDEQ or that Ford/KPC, or the IMK facility will necessarily be released from actual or potential limit and/or monitoring conditions in their respective NPDES permits.

Please contact Mr. Bruce Walker or Mr. Chris Austin if you have questions on the above comments, or you may contact us.

Sincerely,

Clifton Clark

Subject:
Summary of Analyses for Dioxins and Furans, Ford/Kingsford Site, Kingsford, Michigan.

Dear Messrs. Dell and Saalfeld:

ARCADIS is pleased to submit this document on behalf of Ford Motor Company (Ford) and The Kingsford Products Company (KPC), to provide a summary of the analytical results for the groundwater and pretreatment system samples collected for analysis of polychlorinated dibenzo-p-dioxins (dioxins) and polychlorinated dibenzofurans (furans) in accordance with Attachment D, Work Plan for Additional Dioxin/Furan Monitoring, Full-Scale Groundwater Treatment System, National Pollutant Discharge Elimination System (NPDES) Permit Application, Ford/Kingsford Site, Kingsford, Michigan (Work Plan) dated October 14, 2004. The Work Plan had been previously submitted to, reviewed, and approved by the Michigan Department of Environmental Quality (MDEQ) prior to sampling. These samples were collected to support the NPDES permit application for the full-scale groundwater treatment system for the subject site that is currently under construction.

Sampling Events

Groundwater samples were collected from select shallow and deep wells located along and away from the Menominee River, as identified in the Work Plan, in October 2004. The second sampling event was completed in December 2004. Groundwater samples were collected from all of the sampling points outlined in the Work Plan, except for Monitoring Well GM-64B which has not been re-installed (it

was formerly located in the vicinity of the full-scale treatment system, currently a high activity construction area). The wells sampled were selected to provide lateral and vertical coverage (Zones A, B, C, and D).

A total of thirty-one samples were collected during each sampling event for laboratory analysis of dioxins and furans using United States Environmental Protection Agency (U.S. EPA) Method 1613, Revision B *"Tetra- through Octa-Chlorinated Dioxins and Furans by Isotope Dilution HRGC/HRMS"* (October 1994). Nineteen samples were collected from monitoring wells, groundwater extraction wells and the groundwater pretreatment system effluent. In addition, nine (9) field blanks and three (3) equipment blanks were also submitted for analysis during each event. These samples were submitted to check for potential procedural contamination and to assess the quality of data from the field sampling program.

Enough sample volume was collected for each sample location to submit split samples to Severn Trent Laboratory (STL) in Knoxville, Tennessee and to Alta Analytical (Alta) in El Dorado Hills, California. The purpose of the split samples was to provide an additional level of quality control, and provide a metric for comparing each laboratory's sample preparation and analytical capabilities. Each laboratory was provided with specific guidelines for sample preparation, analysis and reporting. A copy of these instructions is provided in Attachment A.

Summary of Analytical Results

As requested by the MDEQ, each laboratory reported the samples in two separate reports based on proximity to the Menominee River. Wells located adjacent to the river (Pretreatment) and wells located away from the river (Full-Scale). The results of Pretreatment samples were presented by STL in laboratory reports H4K060104 (October 2004) and H4L230143 (December 2004) and by Alta in laboratory reports 25386 (October 2004) and 25520 (December 2004). The results of Full-Scale samples were presented by STL in laboratory reports H4K060107 (October 2004) and H4L230147 (December 2004) and by Alta in laboratory reports 25446 (October 2004) and 25519 (December 2004). Both laboratories concurrently submitted a copy of these reports to Gerry Saalfeld and Chris Austin of the MDEQ and Ric Studebaker of ARCADIS.

The analytical results were tabulated in accordance with the Work Plan to facilitate data review. A summary of the toxicity equivalency concentration (TEC) calculations for each sample is presented in Table 1. The Pretreatment and Full-Scale analytical results and TEC calculations are presented in Tables 2 and 3, respectively. Results of the equipment blanks, field blanks, and laboratory quality control samples are presented in Tables 4, 5, and 6, respectively. Corrections were made to address method blank detections as specified in the Work Plan. For

example, in situations when a congener was detected in both the sample and the corresponding method blank, the method blank concentration was subtracted from the sample concentration. If the method blank concentration was higher than the sample concentration, the sample concentration was reported as less than "<" the original sample concentration (note that this adjusted concentration was treated as a zero in the subsequent TEC calculations). Adjusted concentrations are denoted in the table with a shaded cell. In accordance with the Work Plan, the summary tables with the raw data (e.g. the adjustment was not made to address the method blank detected concentrations) and the subsequent TEC calculations are presented in Attachment B as Tables B1 through B6.

The analytical results indicate that the samples were generally free of dioxin and furans. Of the detected congeners, octa- and hepta-congeners (e.g., OCDF, OCDF, HpCDD, HpCDF) were the most commonly detected, and were detected at low levels in several of the groundwater samples, field blanks, and method blanks. Additional congeners (e.g. PeCDD, HxCDD, and HxCDF) were detected at low levels in the samples collected from Monitoring Wells GM-62B and GM-72A. All samples were non-detect for 2,3,7,8-TCDD.

The analytical results between the two laboratories were consistently equivalent. However, during the December 2004 sampling event, HxCDF congeners were detected in five (GWGMEW-3, GWGMEW-9, GWGM-72A, EBGWGM-62C and GWGM-62C) samples and in the method blank reported by STL that were inconsistent with the results of the split and the October 2004 sampling event. As a result, these samples were re-extracted and analyzed. With the exception of one sample (GWGM-72A), the results of the re-extracted sample yielded non-detect results for HxCDF, suggesting that the presence of this congener in these samples was a laboratory artifact and illustrating the potential for false positives at extremely low detection levels.

Results of the equipment blanks, field blanks, and method blanks were reviewed for procedural sources of dioxin contamination. As indicated above, octa- and hepta-congeners were detected at low levels in some of the blank samples. Since the congeners identified and concentrations detected in the equipment and field blanks were comparable with the method blanks this data suggests that the field procedures employed to collect and ship the samples did not have an affect on the results.

TEC Calculations

Consistent with previous data submittals, TEC calculations were completed for all of the samples, field blanks, equipment blanks and method blanks. These calculations are presented for each sample, and a summary of TEC calculations are presented in Table 1. MDEQ staff defines level of concern as a TEC of 0.0086 parts per

quadrillion (ppq) for all congeners (the threshold specific to the 2,3,7,8-TCDD congener is not applicable since all data was non-detect). Corrections were made to address method blank detections, as indicated above, prior to performing the TEC calculation. Adjusted concentrations are denoted in the table with a shaded cell. Raw data and TEC calculations are presented in Appendix B as Tables B1 through B6.

The samples collected from three sampling locations have resulted in a TEC calculation value above the threshold value of 0.0086 ppq. These samples were collected from Monitoring Wells GM-62B, GM-62C, and GM-72A, which are located away from the Menominee River and are not part of the required groundwater extraction area. Samples collected from Monitoring Well GM-62B yielded a TEC of 0.57464 ppq from Alta and 0.27504 ppq from STL in October 2004. The December 2004 sampling results yielded a TEC of 0.04727 ppq from STL and the result from Alta was below the threshold at 0.00835 ppq. It should be noted that the December 2004 results for Monitoring Well GM-62B are one to two orders of magnitude lower than the October 2004 results for both laboratories. Further, the Alta result was below the threshold value. The range of TEC calculation values for samples collected from this well is attributed to the presence of sediment disturbed from the bottom of the well during the October 2004 sampling event. Additional precautions were taken during the December 2004 sampling event not to disturb the sediment, and this is reflected in the results.

In addition to Monitoring Well GM-62B, one sample collected from Monitoring Wells GM-62C and GM-72A was detected above the threshold value. In October 2004, the sample collected from Monitoring Well GM-62C yielded a TEC of 0.01521 ppq from Alta (the sample from STL was below the threshold at 0.00385 ppq). The Monitoring Well GM-62C samples in December 2004 were both below the threshold value and yielded a TEC of 0.00496 and 0.00125 from Alta and STL, respectively. Conversely, the December 2004 sample collected from Monitoring Well GM-72A yielded a TEC of 0.00880 from STL, which was slightly above the threshold and likely influenced by matrix interferences as discussed below. Comparatively, the Alta split sample from Monitoring Well GM-72A in December 2004 yielded a TEC of 0.00394 from Alta, below the threshold value. In October 2004, samples collected from Monitoring Well GM-72A yielded a TEC of 0.00046 ppq from Alta and 0.00000 ppq from STL, both below the threshold value.

Two method blanks from STL yielded a TEC that is one order of magnitude above the threshold value of 0.0086 ppq. The elevated TEC in both blanks was based on the presence of 2,3,4,6,7,8-HxCDF at a peak of 1.3 ppq in Method Blank 4323358 and 0.43 ppq in Method Blank 5012114. In October 2004, this congener was not detected in any other sample or blank. In December 2004, as previously described, HxCDF was detected in five samples which were subsequently re-extracted and re-analyzed in the STL data set. With the exception of one sample, HxCDF was not

detected in the re-extracted samples. In both cases, it was concluded that the peak was associated with matrix interferences (e.g., laboratory contaminant or artifact, instrument noise, etc.). The STL method blanks strongly demonstrate how matrix interferences can contribute significantly to the TEC.

Results Evaluation

All of the samples collected along the river to address MDEQ concerns regarding the potential for discharge of dioxins/furans from the existing pretreatment system to the Iron Mountain/Kingsford wastewater treatment plant yielded results that were below levels of concern.

Data yielding a TEC above 0.0086 ppq were found in groundwater samples collected from Monitoring Wells GM-62B, GM-62C, and GM-72A. Monitoring Wells GM-62B and GM-62C represent a monitoring well nest and are located downgradient of Monitoring Well GM-72A (which is located within the source area) and upgradient of the nested Monitoring Wells GM-37A and GM-37B. Only one of the four groundwater samples collected from Monitoring Well GM-62C, which is screened below Monitoring Well GM-62B, resulted in a TEC above the threshold value. Groundwater samples collected from Monitoring Well GM-72A, also yielded only one TEC which was slightly above the threshold value. The downgradient Monitoring Wells GM-37A and GM-37B yielded laboratory results that were below levels of concern. The upgradient and downgradient wells (in reference to the source area) indicated that there may be a localized area near Monitoring Well GM-62B with slightly elevated concentrations or that the data collected from this well is anomalous. Based on the variability observed between samples, it appears likely that the concentrations are the result of sediment disturbances from sampling activities and are thus not indicative of a mobile source of dioxins/furans.

Monitoring Wells GM-62B and GM-62C, which yielded results that were above levels of concern, are located more than 2,800 feet from the river. It is our understanding that 1,000 feet is the rule-of-thumb distance threshold employed by MDEQ in their dioxin/furan determinations (e.g., dioxins/furans are not expected to migrate 1,000 feet in groundwater given their hydrophobic properties). Refer to Figure 1 for a depiction of the site with the location of the wells and a summary of the TEC results.

Monitoring Wells GM-62B and GM-62C are located more than 2,000 feet away from the full-scale treatment system extraction well network. Groundwater velocities calculated for the permeable material at the site range from 3 to 280 feet per day (ft/day). Based on groundwater flow, dioxins and furans should have reached the full-scale treatment system extraction well network within 2 years. However,

dioxins and furans are hydrophobic and not particularly mobile since they adhere strongly to the soil matrix.

In addition, the environmental conditions at the Northeast Pit have existed for approximately 75 years and are stabilized. Furthermore, the recent completion of the Northeast Pit interim response action placed an impermeable cover over the Northeast Pit, which will reduce or eliminate the potential for any continued introduction of contaminants into the groundwater via infiltration through waste materials. Therefore, it is extremely unlikely that conditions at Monitoring Well GM-62 will cause any detectable changes at the river area regarding dioxins and furans.

Finally, the groundwater along the river that will be captured by the full-scale treatment system extraction well network has been shown to be below levels of concern for dioxins/furans. Therefore, the monitoring requirements contained in the draft NPDES permit for the full-scale groundwater treatment system are too restrictive as written. The data do not support a conclusion that there is any reasonable potential for the system effluent to exceed levels of concern, let alone any applicable water quality based effluent limitations.

Conclusions

Based on the results discussed above, the following conclusions can be reached for the Ford/Kingsford Site.

- All samples were non-detect for 2,3,7,8-TCDD.

- The data indicates that operation of the existing pretreatment system was not a source of dioxins/furans above levels of concern, as it pertains to the Iron Mountain/Kingsford wastewater treatment plant. In fact, pretreatment effluent sample results were non-detect for all congeners with the exception of the octa-congener for both dioxin and furan in the October 2004 split sample submitted to STL, which resulted in a TEC value that was at least one order of magnitude below the MDEQ level of concern.

- The October and December 2004 data indicate that dioxins/furans are not present at levels of concern in groundwater along the Menominee River. These results are consistent with the findings from the historical U.S. EPA Method 1613B data for samples collected in 2003 at the pretreatment system and monitoring wells/extraction wells along the Menominee River.
- The low concentrations in Extraction Well GMEW-7 (e.g., near the instrument detection limit) of octa- and hepta-congeners yield a slightly elevated TEC

(compared to other wells) that is anamolous to the data set due to the ubiquitous nature of these congeners. Further proof of the ubiquitous nature of the octa- and hepta-congeners is found in their detections in the method, field, and equipment blanks.

- All samples are far below the minimum level for analytical results.
- Ford and KPC have performed a considerable amount of dioxin/furan monitoring at a significant cost.

Closing

Ford, KPC, and ARCADIS appreciate MDEQ's cooperation on this issue. If you have questions regarding this submittal or require any further information, please contact either of the undersigned.

Sincerely,

ARCADIS G&M, Inc.

ppq Parts per quadrillion (picograms per liter).
TEC Toxicity equivalence concentration of 2,3,7,8-TCDD.
Bold Calculated value is above the threshold value of 0.0086 ppq.

All values are reported in parts per quadrillion (ppq).

BEF Bioaccumulation equivalency factor [MDEQ, Rule 323.1209(4)(ii)].

DL Detection limit.

ND Congener was not detected; contribution to the TEC is zero.

ppq Parts per quadrillion (picograms per liter).

QL Congener quantitation limit for that sample.

TEC Toxicity equivalence concentration of 2,3,7,8-TCDD.

TEF Toxicity equivalency factor [MDEQ, Rule 323.1209(4)(ii)].

Result adjusted for method blank contamination (i.e. the method blank result was subtracted from the original result).

* TEC (ppq) = Detected result (ppq) × BEF × TEF

Data Qualifiers:

B Compound was detected in the associated QC method blank sample.

J Concentration is qualified as estimated.

P Does not meet all the method specified congener identification criteria.

All values are reported in parts per quadrillion (ppq).

BEF Bioaccumulation equivalency factor [MDEQ, Rule 323.1209(4)(ii)].

DL Detection limit.

ND Congener was not detected; contribution to the TEC is zero.

ppq Parts per quadrillion (picograms per liter).

QL Congener quantitation limit for that sample.

TEC Toxicity equivalence concentration of 2,3,7,8-TCDD.

TEF Toxicity equivalency factor [MDEQ, Rule 323.1209(4)(ii)].

Result adjusted for method blank contamination (i.e. the method blank result was subtracted from the original result).

* TEC (ppq) = Detected result (ppq) × BEF × TEF

Data Qualifiers:

B Compound was detected in the associated QC method blank sample.

J Concentration is qualified as estimated.

P Does not meet all the method specified congener identification criteria.

All values are reported in parts per quadrillion (ppq).

BEF Bioaccumulation equivalency factor [MDEQ, Rule 323.1209(4)(ii)].

DL Detection limit.

ND Congener was not detected; contribution to the TEC is zero.

ppq Parts per quadrillion (picograms per liter).

QL Congener quantitation limit for that sample.

TEC Toxicity equivalence concentration of 2,3,7,8-TCDD.

TEF Toxicity equivalency factor [MDEQ, Rule 323.1209(4)(ii)].

Result adjusted for method blank contamination (i.e. the method blank result was subtracted from the original result).

* TEC (ppq) = Detected result (ppq) × BEF × TEF

Data Qualifiers:

B Compound was detected in the associated QC method blank sample.

J Concentration is qualified as estimated.

P Does not meet all the method specified congener identification criteria.

All values are reported in parts per quadrillion (ppq).

BEF Bioaccumulation equivalency factor [MDEQ, Rule 323.1209(4)(ii)].

DL Detection limit.

ND Congener was not detected; contribution to the TEC is zero.

ppq Parts per quadrillion (picograms per liter).

QL Congener quantitation limit for that sample.

TEC Toxicity equivalence concentration of 2,3,7,8-TCDD.

TEF Toxicity equivalency factor [MDEQ, Rule 323.1209(4)(ii)].

Result adjusted for method blank contamination (i.e. the method blank result was subtracted from the original result).

* TEC (ppq) = Detected result (ppq) × BEF × TEF

Data Qualifiers:

B Compound was detected in the associated QC method blank sample.

J Concentration is qualified as estimated.

P Does not meet all the method specified congener identification criteria.

Footnotes on Page 5.

Table 6. Dioxin and Furan 2,3,7,8-TCDD Equivalency Calculations for 2004 Method Blanks, Ford/Kingsford Site, Kingsford, Michigan.

All values are reported in parts per quadrillion (ppq).

BEF	Bioaccumulation equivalency factor [MDEQ, Rule 323.1209(4)(ii)].
DL	Detection limit.
ND	Congener was not detected; contribution to the TEC is zero.
ppq	Parts per quadrillion (picograms per liter).
QL	Congener quantitation limit for that sample.
TEC	Toxicity equivalence concentration of 2,3,7,8-TCDD.
TEF	Toxicity equivalency factor [MDEQ, Rule 323.1209(4)(ii)].
	Result adjusted for method blank contamination (i.e. the method blank result was subtracted from the original result).

TEC (ppq) = Detected result (ppq) × BEF × TEF

Data Qualifiers:

B	Compound was detected in the associated QC method blank sample.
J	Concentration is qualified as estimated.
P	Does not meet all the method specified congener identification criteria.

ATTACHMENT A
Guidelines for Analysis and Reporting of Dioxin Samples Collected From the Ford/Kingsford Site.

Dioxin samples collected from the Ford/Kingsford site will be analyzed and reported according to the information contained within this memo. It is anticipated that there will be two sampling events each consisting of approximately 20 primary samples, five field blanks, and two equipment blanks. The proposed schedule for the sampling is the collection of the first round during the third or fourth week of October 2004, and the collection of the second round during the first or second week of December 2004. A third sampling round, consisting of approximately seven primary samples, three field blanks, and two equipment blanks, will be collected during 2005. Three liters of groundwater will be collected at each sample location to ensure that two or three analytical runs can be performed per sample, if needed.

The following information is provided to support the analysis of these samples:

1) Samples will be run by United States Environmental Protection Agency (U.S. EPA) Method 1613B.

2) Samples will be run in the sampling order, based on chain-of-custody sampling date and time. Samples will be held until all samples are received for each sampling event. Approximately 27 will be received by the laboratory for the first two sampling rounds and 12 samples for the third sampling round. A representative of ARCADIS will contact the laboratory to confirm that all samples have been received prior to sample extraction and analysis. All samples will be extracted at the same time and then run in two consecutive analytical batches.

3) Samples will be run for the 17 congeners listed on Table 1 of U.S. EPA Method 1613B. Totals will not be reported since these may include other dioxin/furans not listed on this table.

4) A low-level quality control (QC) check sample (as referenced in Sections 7.16 and 9.6 of U.S. EPA Method 1613B) will be analyzed immediately before the analysis of the samples from the first sampling round and the third sampling round (at a minimum). This sample will be analyzed with any other QC samples (e.g. laboratory control sample) prior to the method blank and the samples submitted for analysis. To address contaminant carryover, a rinse sample will be run between the QC samples and the method blank.

5) A second method blank will be run with each analytical batch (e.g., a total of four method blanks for each of the first two sampling events and a total of two method blanks for the third sampling event).

6) Congener Identification: Per Section 16.0 of U.S. EPA Method 1613B, all of the identification criteria must be met before a peak can be identified as a dioxin/furan congener (in a standard, blank, or sample). If any single identification criteria (or combination) is outside the acceptable range, the peak is not a dioxin/furan congener, and the analyte must be identified as a non-detect with a QC flag. Congener identification criteria from U.S. EPA Method 1613B are as follows:

a) The signals for the two exact mass to charge ratios (m/z) specified in Table 8 of U.S. EPA Method 1613B must be present and must maximize within the same two seconds.

b) The signal-to-noise ratio (S/N) must be above 2.5 for all suspected dioxin/furan peaks.

c) Ion abundance ratios must be within the limits specified in Table 9 of U.S. EPA Method 1613B.

d) Relative retention times for 2,3,7,8-substituted chlorinated dibenzo-p-dioxin and chlorinated dibenzofuran must be within the limits specified in Table 2 of U.S EPA Method 1613B.

e) Confirmatory analysis must be performed for any peaks identified as 2,3,7,8-tetrachlorodibenzofuran using the gas chromatograph columns specified in U.S. EPA Method 1613B.

Note: Peaks that meet the retention time **and** signal-to-noise criteria described above, but **do not** meet the remaining congener identification criteria will be reported as non-detect and the elevated detection limit flagged indicating that the "Does not meet all the method specified congener identification criteria."

The following information is provided to support the reporting of these samples:

1) The laboratory will group the "pretreatment" and "full-scale" samples in separate laboratory reports. The attached table (Table A-1) identifies the samples as "pretreatment" or "full-scale."

2) In addition to the reporting requirements specified in U.S EPA Method 1613B, the laboratory will be required to report the method detection limit (e.g., EDL).

3) If preliminary results show the presence of detectable levels of dioxins/furans, the laboratory will immediately forward these data to ARCADIS. ARCADIS will notify the MDEQ of these preliminary findings within seven days.

4) The laboratory reports will consist of a full data package and include: narrative explaining qualified (flagged) results, initial calibration (ICAL), continuing calibrations (CCALs), method blanks (MB), ongoing precision and recovery (OPR), sample raw data, confirmation data (if applicable), quality control and sample datasheets, sample preparation bench sheets, and receiving documents (e.g., chain of custody, sample receiving checklist, etc.).

5) A final copy of each laboratory report will be distributed by the laboratory to the following three individuals:

Ric Studebaker
ARCADIS
126 N. Jefferson Street Ste. 400
Milwaukee, Wisconsin 53202

Gerald Saalfeld
Water Division
Michigan Department of Environmental Quality
MDEQ-Water Division, 2 South
525 West Allegan
Lansing MI 48933

Chris Austin
Michigan Department of Environmental Quality
Remediation and Redevelopment Division
1420 West US Hwy. 2
Crystal Falls, MI 49920-9623

6) Each laboratory report will also be reported electronically as a portable document format (PDF) and in electronic data deliverable (EDD) format.

The following data review actions are anticipated:

- Matrix interferences are sometimes observed in the method blanks. Per U.S. EPA Method 1613B, method blanks should be free from contamination or matrix interferences (e.g., there should be non-detects for all congeners). If excessive method blank contamination occurs, or if 2,3,7,8-TCDD is detected in a method blank, the samples associated with the method blank will be re-extracted, cleaned up, and re-run in accordance with U.S. EPA Method 1613B and each laboratory's corrective action procedures. Excessive blank contamination is defined to be detection of congeners at concentrations that are out of control relative to the laboratory's historic blank analyses.

- If unacceptable contamination is found in the field or equipment blanks, samples with detections associated with the blanks will be disqualified as invalid data and will be resampled. Samples that are non-detect will be valid since these samples were not affected by potential field procedures.

Table B1. Summary of Dioxin/Furan Samples Collected in 2004, Ford/Kingsford Site, Kingsford, Michigan.

All values are reported in parts per quadrillion (ppq).

BEF Bioaccumulation equivalency factor [MDEQ, Rule 323.1209(4)(ii)].

DL Detection limit.

ND Congener was not detected; contribution to the TEC is zero.

ppq Parts per quadrillion (picograms per liter).

QL Congener quantitation limit for that sample.

TEC Toxicity equivalence concentration of 2,3,7,8-TCDD.

TEF Toxicity equivalency factor [MDEQ, Rule 323.1209(4)(ii)].

* TEC (ppq) = Detected result (ppq) x BEF x TEF

Data Qualifiers:

B Compound was detected in the associated QC method blank sample.

J Concentration is qualified as estimated.

P Does not meet all the method specified congener identification criteria.

All values are reported in parts per quadrillion (ppq).

BEF Bioaccumulation equivalency factor [MDEQ, Rule 323.1209(4)(ii)].

DL Detection limit.

ND Congener was not detected; contribution to the TEC is zero.

ppq Parts per quadrillion (picograms per liter).

QL Congener quantitation limit for that sample.

TEC Toxicity equivalence concentration of 2,3,7,8-TCDD.

TEF Toxicity equivalency factor [MDEQ, Rule 323.1209(4)(ii)].

* TEC (ppq) = Detected result (ppq) × BEF × TEF

Data Qualifiers:

B Compound was detected in the associated QC method blank sample.

J Concentration is qualified as estimated.

P Does not meet all the method specified congener identification criteria.

All values are reported in parts per quadrillion (ppq).

BEF Bioaccumulation equivalency factor [MDEQ, Rule 323.1209(4)(ii)].
DL Detection limit.
ND Congener was not detected; contribution to the TEC is zero.
ppq Parts per quadrillion (picograms per liter).
QL Congener quantitation limit for that sample.
TEC Toxicity equivalence concentration of 2,3,7,8-TCDD.
TEF Toxicity equivalency factor [MDEQ, Rule 323.1209(4)(ii)].

* TEC (ppq) = Detected result (ppq) × BEF × TEF

Data Qualifiers:

B Compound was detected in the associated QC method blank sample.
J Concentration is qualified as estimated.
P Does not meet all the method specified congener identification criteria.

All values are reported in parts per quadrillion (ppq).

BEF Bioaccumulation equivalency factor [MDEQ, Rule 323.1209(4)(ii)].

DL Detection limit.

ND Congener was not detected; contribution to the TEC is zero.

ppq Parts per quadrillion (picograms per liter).

QL Congener quantitation limit for that sample.

TEC Toxicity equivalence concentration of 2,3,7,8-TCDD.

TEF Toxicity equivalency factor [MDEQ, Rule 323.1209(4)(ii)].

* TEC (ppq) = Detected result (ppq) × BEF × TEF

Data Qualifiers:

B Compound was detected in the associated QC method blank sample.

J Concentration is qualified as estimated.

P Does not meet all the method specified congener identification criteria.

Table B6. Dioxin and Furan 2,3,7,8-TCDD Equivalency Calculations for 2004 Method Blanks, Ford/Kingsford Site, Kingsford, Michigan.

All values are reported in parts per quadrillion (ppq).

BEF	Bioaccumulation equivalency factor [MDEQ, Rule 323.1209(4)(ii)].
DL	Detection limit.
ND	Congener was not detected; contribution to the TEC is zero.
ppq	Parts per quadrillion (picograms per liter).
QL	Congener quantitation limit for that sample.
TEC	Toxicity equivalence concentration of 2,3,7,8-TCDD.
TEF	Toxicity equivalency factor [MDEQ, Rule 323.1209(4)(ii)].

* TEC (ppq) = Detected result (ppq) x BEF x TEF

Data Qualifiers:

B	Compound was detected in the associated QC method blank sample.
J	Concentration is qualified as estimated.
P	Does not meet all the method specified congener identification criteria.

100% recycled paper produced by wind power energy

Appendix N

Whole Groundwater Toxicity Testing

This appendix summarizes the results of groundwater and seep toxicity testing for the Ford/Kingsford site and discusses the relationship between toxicity and chemistry results. The primary classes of chemicals contributing to toxicity are identified, and their relative importance is qualitatively discussed.

Introduction

At the request of the MDEQ, ARCADIS G&M, Inc. conducted toxicity testing and chemical analyses of groundwater samples collected from wells located near the Menominee River. The tests were conducted using standard methods developed for whole-effluent toxicity (WET) testing. Limited additional testing was conducted directly by the MDEQ. A total of 78 toxicity tests were conducted, encompassing two test species (fathead minnows and *Daphnia magna*), 22 groundwater wells, and two seep locations. Standard Toxicity Identification Evaluation (TIE) procedures were conducted for seven water samples (six groundwater and one seep) to facilitate the identification of chemicals contributing to toxicity. Complete toxicity test and TIE results are provided by AScI (1999; 2000a,b) and New England Bioassay (2000a-e). Chemistry results are included in Tables 6-16 and 6-18 of this Remedial Investigation (RI) report.

The WET test methods used in this investigation were originally developed for monitoring of effluent discharges, for the purpose of protecting biological community quality in the receiving waters. During the past several years, the U.S. Environmental Protection Agency (EPA) and others have embarked on a mid-course review of WET testing (Ausley, 2000). Based on a technical review of the merits and limitations of WET testing, the most appropriate use of this type of information is as an indicator of the need for further evaluation of risks to aquatic life (Chapman, 2000). Due to factors such as the inability to reliably predict instream biological conditions from WET test results (Diamond and Daley, 2000), variability of test results (Warren-Hicks et al., 2000; Moore et al., 2000a), and the potential for false positives (Moore et al., 2000b), WET testing does not provide a definitive determination of ecological impact (Chapman, 2000).

In contrast to WET testing, groundwater toxicity testing has little precedent in the technical literature, and the ability to predict ecological impacts based on groundwater toxicity test results has not been evaluated. However, it is reasonable to expect that the predictive ability of groundwater toxicity testing is lower than that of WET testing, because of the diffuse nature of groundwater discharge and inherent differences in the geochemistry of groundwater versus surface water. Given the important uncertainties associated with WET test methodologies and the additional uncertainty associated with groundwater toxicity testing, the results summarized in this appendix should be viewed not as an end in themselves, but rather as a means of focusing further investigations of potential risks to aquatic life in the Menominee River (see Appendix J).

Groundwater Toxicity Test Results

The groundwater toxicity test results are summarized in Table N-1. The test results are summarized as toxic unit (TU) values, which correspond to the amount of dilution with clean laboratory water that is required to

Because we care
100% recycled paper produced by wind power energy

achieve a specified level of test organism response. Acute TU (TU_A) values are based on a specified response of 50% mortality. A TU_A less than 1.0 indicates less than 50% mortality in the undiluted sample and is viewed by MDEQ as acceptable for discharge to surface waters. For certain samples, TU values were also calculated for 50% *Daphnia magna* immobilization (where this response was observed). Daphnid immobilization is considered equivalent to mortality for the purpose of calculating acute water quality criteria (Stephan et al., 1985).

Split sampling and/or repeated toxicity testing were implemented for nine groundwater wells and one seep location. The TU values varied considerably among tests, and in several cases the classification of samples as toxic (TU > 1.0) or nontoxic (TU < 1.0) varied among tests. Toxicity was observed even in one sample collected from GM-26B, which was selected as an uncontaminated reference well based on previous chemical analyses. One factor contributing to the observed variation in toxicity test results was likely a difference in test procedures between laboratories. Specifically, New England Bioassay acclimated the *Daphnia magna* test organisms to very hard water conditions prior to toxicity testing, per USEPA guidance (USEPA, 1993), whereas AScI Corporation omitted this procedure. Test organism acclimation reduces stress related to water hardness and provides a result that is more indicative of the toxicity of constituents of interest in the water sample. Additionally, variability and false positives are recognized as one of the limitations of WET test procedures (Warren-Hicks et al., 2000; Moore et al., 2000a; Moore et al., 2000b).

The results shown in Table N-1 support the following conclusions:

- Groundwater samples collected to the northwest of GM-5 and to the southwest of GM-27 did not consistently exhibit toxicity (TU > 1.0);
- Between GM-5 and GM-27, seven of twelve groundwater wells (GM-5, GM-25A, GM-25B, GM-26A, GM-26C, GM-27A, and GM-EW3) and one of two seeps (SP-2) exhibited toxicity (TU > 1.0);
- Groundwater collected from GM-25B and extraction well GM-EW3 required between five and sixteen-fold dilution to achieve less than 50% mortality; and
- Dilution of approximately two-fold or less was generally sufficient to achieve less than 50% mortality for the remaining toxic samples.

Toxicity Identification Evaluation (TIE) Results

The identity of chemicals contributing to groundwater toxicity was investigated using standard USEPA methods for a "Phase I" TIE, which involve specific manipulations of the sample, designed to remove toxicity due to certain classes of chemicals. Initially, a TIE was conducted for GM-25B groundwater using more than 20 different sample manipulations. The procedures which lowered toxicity in GM-25B groundwater included solid phase extraction with a C18 column, indicating a contribution to toxicity due to hydrophobic organic chemicals, and addition of EDTA, indicating a contribution to toxicity due to metals.

Because we care
100% recycled paper produced by wind power energy

Subsequent TIE testing was limited to these procedures.[1] The results of the TIE tests are summarized in Table N-2.

In most cases, the TIE results indicated toxicity due to a combination of hydrophobic organic chemicals and metals. However, the treatments which achieved a TU_A less than 1.0 did not completely eliminate toxicity in most cases. Combined removal of organic compounds and addition of EDTA generally resulted in survival of 60-80% for both test species. The TIE results do not distinguish whether incomplete removal of metal toxicity or an uncharacterized source of toxicity (such as major ions; see below) was responsible for the residual toxicity. Removal of hydrophobic organic compounds was believed to be essentially complete, based on the use of a large volume of sorbent in the C18 column.

Procedures that did not reduce toxicity in the GM-25B TIE are also of interest, as they indicate classes of chemicals that were not important contributors to the observed toxicity. For example, toxicity due to particulate material was suspected in samples where a precipitate was evident; however, filtration did not reduce toxicity. Aeration also did not reduce toxicity, indicating that volatile compounds were not important contributors to toxicity.

Identification of Toxicants

Chemicals contributing to observed groundwater toxicity are identified based on an evaluation of the TIE and analytical chemistry results. Three important groups of chemicals identified as contributors to toxicity are phenolic compounds, iron, and major ions. These chemicals are discussed below, followed by a brief discussion of other chemicals which were detected but probably did not play an important toxicological role.

Phenolic Compounds

Table N-3 summarizes the concentrations of phenolic compounds in the groundwater samples tested for toxicity. Elevated concentrations of 2,4-dimethylphenol were detected in all TIE samples. However, the 2,4-dimethylphenol concentration exceeded MDEQ's Final Acute Value (FAV) only in GM-25B groundwater. Monomethylphenols and phenol also exceeded the respective FAVs in GM-25B but were generally not detected in the other samples. While the FAV values for phenolic compounds are useful for screening purposes, their derivation incorporates data for a variety of species, as well as uncertainty factors. The LC50s measured directly for fathead minnows and *Daphnia magna* provide a more accurate means of assessing toxicity to these species and are summarized in Table N-4.

Although the LC50s for individual phenolic compounds were not exceeded in GM-25B groundwater, the combined concentrations were clearly sufficient to cause toxicity on an additive basis, even in the absence of other chemicals. However, the concentrations of 2,4-dimethylphenol (or in the case of GM-26A, 2,4-dimethylphenol and 3- and 4-methylphenol combined) were well below the LC50s for either test species in all other samples. For fathead minnows, the concentrations of phenolic compounds were between 5% and

[1] An ion exchange procedure was also implemented for seep sample SP-2; results were inconclusive.

Because we care
100% recycled paper produced by wind power energy

15% of the LC50. For *Daphnia magna*, the concentrations of phenolic compounds ranged from 20% to nearly 50% of the LC50.

Thus, the reported concentrations of phenolic compounds in most samples do not clearly account for the toxicity attributed to organic compounds in the TIE. The apparent discrepancy could be due to unmeasured organic compounds (e.g., complex compounds related to lignin degradation; Higashi et al., 1992), or it may reflect the cumulative effect of phenolic compounds, iron, and major ions. These two explanations cannot be distinguished based on the TIE results, because toxicity due to major ions was not affected by the TIE procedures, and iron toxicity may not have been completely removed. However, the analysis of iron and major ion concentrations is consistent with cumulative toxicity (see below).

Iron

Despite TIE results implicating metals as important toxicants, none of the metal concentrations reported for the groundwater samples exceeded the respective FAV levels. However, MDEQ has not adopted an FAV for iron, which was detected at concentrations ranging from 260 to 120,000 µg/l (Table N-3). Iron LC50s for aquatic organisms were identified from U.S. EPA's AQUIRE database, as shown in Table N-5. With the exception of dissolved iron in seep sample SP-2, iron concentrations were within the range of LC50s reported for *Daphnia magna* and other species. The total iron concentration in seep sample SP-2 (approximately 30 mg/kg; A. Stewart, STL-Savannah, personal communication) was within the range of *Daphnia magna* LC50s. Iron LC50s were not identified for fathead minnows.

Interpretation of the relationship between iron concentrations and toxicity is somewhat complicated by the fact that iron tends to precipitate out of solution under aerobic conditions. However, it is evident from the toxicity data shown in Table N-5 that iron concentrations can be maintained in water at levels sufficient to cause acute toxicity. Extensive precipitation was observed in GM-25B groundwater, which contained the highest iron concentration upon sample collection (Table N-3). Seep sample SP-2 also exhibited settling of particulate material during the course of the toxicity tests. The toxicity testing laboratory did not observe precipitation in the remaining groundwater samples.

The identification of iron as a contributor to the observed groundwater toxicity is generally consistent with the results of the TIE. Although EDTA most strongly reduces the toxicity of metals such as cadmium, copper, lead, nickel, and zinc, it is known to weakly reduce the toxicity of other metals such as manganese (Hockett and Mount, 1996) and would be expected to weakly reduce the toxicity of iron as well. The apparent lack of metal toxicity to fathead minnows in GM-25B groundwater is surprising, given the very high iron concentration and the contribution of metals to *Daphnia magna* toxicity in this sample. However, the bioavailable iron concentration in the GM-25B sample was clearly reduced by precipitation. Among the remaining groundwater TIE samples, two samples required a higher EDTA concentration to achieve a TU_A of <1.0 and also contained the highest iron concentrations (GM-25A and GM-27A).

Major Ions

In fresh water, the major ions which constitute total dissolved solids are typically calcium, potassium, magnesium, sodium, chloride, bicarbonate, and sulfate. The TIE samples all contained high concentrations

Because we care
100% recycled paper produced by wind power energy

of major ions, as indicated by high hardness, alkalinity, and conductivity values. The standard TIE procedures implemented as part of this investigation do not directly address major ion toxicity. However, well-developed methods are available to evaluate the toxicity of major ions to fathead minnows and *Daphnia magna*. Specifically, Mount et al. (1997) developed statistical relationships between major ion concentrations and toxicity to fathead minnows, *Daphnia magna*, and *Ceriodaphnia dubia*, based on the results of toxicity tests with over 2,900 ion solutions. These statistical relationships can be applied using the Gas Research Institute's Freshwater Salinity Toxicity Relationship (GRI-FW STR) model (Tietge et al., 1994). Validation studies have indicated that the model is highly accurate for *Ceriodaphnia dubia* but somewhat over-predictive of toxicity for fathead minnows and *Daphnia magna* (Mount et al., 1997).

Predicted LC50 and TU_A values based on major ions alone are summarized for groundwater samples in Table N-6. All of the TIE samples were predicted to be toxic to both test species. Consistent with previous findings, the STR model appears to over-predict toxicity somewhat, given that TU_A values of <1.0 were achieved without the removal of major ions in the TIE. Bicarbonate was the most important of the major ions in contributing to toxicity, based on a comparison to single-salt and double-salt toxicity test results (Mount et al., 1997) as well as model simulations.

Although less toxic than predicted, major ion concentrations probably approached LC50 levels, based on the STR model results. Major ions may account for the residual toxicity observed following organic compound removal and EDTA addition in the TIE. Major ions and phenolic compounds acting as co-stressors may also account for toxicity following EDTA addition, when the reported concentrations of phenolic compounds by themselves were not sufficient to produce the observed level of toxicity. Methods for more accurately determining the relative importance of major ions and other toxicants are available and could be implemented if it becomes important to quantitatively assess the relative contribution of each toxicant to groundwater toxicity (Goodfellow et al., 2000).

Other Chemicals

Several other chemicals were detected in the TIE samples but probably did not contribute significantly to the observed toxicity. Among these, acetic acid is most notable because the concentrations reported for GM-25B and GM-26A groundwater exceeded MDEQ's FAV. The FAV incorporates a safety factor due to the limited number of species tested, but LC50s are available for both fathead minnows and *Daphnia magna* (Rule 57 Aquatic Values Data Sheet for acetic acid). The LC50 for *Daphnia magna* (5,200 mg/L) is higher than the concentrations reported for both groundwater samples, but the LC50s for fathead minnows (79-88 mg/L) were exceeded in GM-25B groundwater. However, toxicity due to acetic acid would most likely be the result of low pH, whereas the pH of GM-25B groundwater (6.02) was not low enough to cause acute toxicity (U.S. EPA, 1986). Additionally, the TIE results for GM-25B do not implicate acetic acid as an important source of toxicity to fathead minnows, as toxicity was eliminated without the removal of acetic acid.

Estimated concentrations of several high molecular weight polycyclic aromatic hydrocarbons (PAHs) were reported for GM-26C groundwater and SP-2 seep water, at concentrations generally exceeding the compounds solubility limits. Presumably the PAHs were adsorbed to suspended solids in the sample; therefore, the bioavailable (dissolved) concentrations in the sample are not known. However, the LC50s of

Because we care
100% recycled paper produced by wind power energy

the detected PAHs are higher than the solubility limits or the detected concentrations, such that their toxicological role in the toxicity tests (if any) would have been limited to that of a secondary stressor (U.S. EPA, 2000).

Other chemicals which were detected in the toxicity test samples but for which FAVs are not available include aluminum, titanium, diethyl ether, and several alcohols and aldehydes. These concentrations were reported in most cases as estimated values (below quantitative detection limits). Toxicity data in the U.S. EPA's AQUIRE database for these chemicals, where available, indicated LC50s that exceeded the reported concentrations. Although data were unavailable for some alcohols and aldehydes, the available data suggested that these classes of chemicals generally exhibited low toxicity (high LC50s). Therefore, these chemicals were considered unlikely to have contributed significantly to the toxicity observed in this investigation.

Summary and Conclusions

A total of 78 groundwater and seep samples were tested for toxicity at the request of MDEQ. The chemicals contributing to observed toxicity were identified based on standard TIE procedures and an evaluation of analytical chemistry results. The findings of this investigation are as follows:

- Groundwater samples collected to the northwest of GM-5 and to the southwest of GM-27 did not consistently exhibit toxicity (TU > 1.0). Seven of twelve groundwater wells and one of two seeps between GM-5 and GM-27 exhibited toxicity (TU > 1.0).

- Dilution of approximately two-fold or less was generally sufficient to achieve less than 50% mortality in groundwater and seep samples, with additional dilution required for samples from GM-25B and GM-EW3.

- Chemicals identified as important contributors to the observed toxicity include phenolic compounds, iron, and major ions (particularly bicarbonate). A semi-quantitative analysis suggests that (1) the measured concentrations of phenolic compounds in most samples were not sufficient to cause acute toxicity but rather acted as co-stressors, (2) iron concentrations may have been sufficient to cause acute toxicity, and (3) major ions probably served as an important co-stressor.

- These results indicate the need for an investigation to determine whether groundwater venting to the Menominee River is adversely affecting biological community quality. Such an investigation has been conducted and is described in Appendix J. No adverse effects on biological community quality in the Menominee River were observed.

a Data are for toxicity tests conducted within 36-h holding time.
b Fathead minnow test initiated 3/7/00 following re-sampling.
c Seep samples KF-CA-2 and SP-2 were collected from the same location.

Table N-2. TIE Procedures that Removed Toxicity from Groundwater or Seep Samples[a]

	GM-5 11/30/99	GM-25A 12/01/99	GM-25B 10/20/99	GM-26A 11/29/99	GM26C 11/30/99	GM-27A 12/01/99	SP-2[b] 06/27/00
Daphnia magna							
C18 column					X		
EDTA							X
C18 + EDTA	X	X	X	X		X	
Residual toxicity	X	X	X	X	X	X	
Fathead minnow							
C18 column			X				
EDTA							
C18 + EDTA	X	X		X	X	X	
Residual toxicity	X	X		X	X	X	

a. Removal of toxicity by sample passage through a C18 column indicates toxicity due to hydrophobic organic compounds. Removal of toxicity by EDTA addition indicates metal toxicity. Residual toxicity indicates either toxicity due to other factors (e.g., major ions) or incomplete removal of metal toxicity. Incomplete removal of organic toxicity was unlikely based on use of a large volume of sorbent.

b. Seep sample SP-2 was not toxic to fathead minnows and was only marginally toxic to *Daphnia magna* (TIE results interpreted based on behavioral endpoints due to high survival).

Table N-3. Concentrations of Phenolic Compounds and Iron in TIE Samples[a]

	GM-5	GM-25A	GM-25B	GM-26A	GM-26C	GM-27A	SP-2
2,4-Dimethylphenol	900	900	3,900	850	2200	890	590
2-Methylphenol	<20	<20	4,800	<20	<50	<20	<5
3-Methylphenol/4-Methylphenol	<20	<20	13,000	350	<50	<20	<5
Phenol	<20	<20	8,000	<20	<50	<20	<5
Iron	11,000	28,000	120,000	24,000	8,100	36,000	260

a Units are µg/L.

Table N-4. Aquatic Toxicity Values for Phenolic Compounds[a]

Chemical	Species Mean Acute Value		Final Acute Value
	Fathead Minnow	*Daphnia magna*	
2,4-Dimethylphenol	17,000	4,800	2,700
2-Methylphenol	14,000	12,000	1,500
3-Methylphenol	55,900	>99,500[b]	1,300
4-Methylphenol	16,500	15,000	570
Phenol	29,500	12,600	3,200

a Values are as listed in MDEQ's Rule 57 Aquatic Values Data Sheets. Species Mean Acute Values represent the geometric mean of LC50s for each species.

b Value is for *Daphnia pulicaria*.

Table N-5. Acute Toxicity of Iron to Aquatic Species[a].

Scientific name	Common name	Duration (days)	LC50 or EC50[b] (µg/L)	Reference

A USGS Groundwater Flow Model Report.

B Hydrogeologic Framework, Areas Exceeding Acute GSI Criteria, and Results of Aquifer Pumping Tests Performed in the Vicinity of the Menominee River.

D R A F T

1. Introduction

ARCADIS, on behalf of Ford Motor Company (Ford) and The Kingsford Products Company (KPC) has prepared a steady-state, three-dimensional groundwater flow model (model) for Kingsford, Michigan. The model was prepared to aid in the design of a groundwater extraction and treatment system to capture groundwater adjacent to the Menominee River in the Study Area where groundwater exceeds acute groundwater surface water interface (GSI) criteria.

The model was developed based on a steady-state, three-dimensional, finite-difference groundwater-flow model prepared by the United States Geological Survey (USGS) and presented in the *Ground-Water Flow and Contributing Areas to Public-Supply Wells in Kingsford and Iron Mountain, Michigan*, (Luukkonen and Westjohn, 2001) (see Appendix A). The model encompasses the communities of Kingsford and Iron Mountain and surrounding areas. The study area location map is shown on Figure 1. The USGS model was refined using site-specific geologic and hydrogeologic data derived from the ongoing remedial investigation and quantitative estimates of hydraulic parameters derived from pumping tests performed by ARCADIS at the Site along the Menominee River between 2001 and 2003 (see Appendix B). The USGS model finite-difference grid was also refined to evaluate the appropriate number and spacing of groundwater extraction wells to be installed along the Menominee River.

1.1 Purpose and Scope

The purpose of this report is to describe the development, calibration, and application of a groundwater flow model of the Study Area located in Kingsford, Michigan

It is critical to develop the purpose and objectives of the groundwater model prior to the model development. The area of the model domain, the dimensions of individual calculation cells, and the process of model calibration depend on the ultimate use of the model. The purpose of this modeling effort is to provide a groundwater flow model capable of simulating groundwater flow within the Study Area at a sufficient level of detail and precision to provide a basis for design of the groundwater extraction and treatment system.

To this end, the groundwater flow model has the following specific initial objectives:

§ Achieve a more complete understanding of the hydrogeologic framework of the Study Area.

- Develop a groundwater flow model that accurately reflects the hydrogeologic conditions at the Site.

- Reliably simulate the groundwater flow system within the vicinity of the Ford/Kingsford Site to simulate and evaluate the potential effects of the installation of a groundwater extraction system.

- Evaluate the installation of groundwater extraction system under several different scenarios.

It is anticipated that the groundwater model will be used to predict the performance of the groundwater extraction system once operation has begun. Additional Site data may be incorporated into the model as it is developed through site investigation and remedial system operation.

DRAFT

2. Conceptual Model

A conceptual groundwater flow model succinctly describes the principal components of a groundwater flow system and is developed from regional, local, and site-specific data. The primary components of a groundwater flow system include (1) areal extent, configuration, and types of aquifers and aquitards, (2) hydraulic properties of aquifers and aquitards, (3) natural groundwater recharge and discharge zones, (4) anthropogenic groundwater sources and sinks, and (5) areal and vertical distribution of groundwater hydraulic head potential. These aquifer system components serve as a framework for the construction of a numerical groundwater flow model.

Prior to constructing the numerical model, a conceptual model was developed to interpret geology, hydrogeology, recharge, surface water, and other factors that may influence the construction of the numerical model. The objective of the conceptual model was to identify the major hydrologic and hydrogeologic processes and boundary conditions that influence the behavior of the groundwater flow system. The conceptual model also served to identify potential data gaps, as well as the various assumptions necessary for the development of the numerical model.

This section describes the geologic and hydrogeologic framework and the conceptual movement of groundwater within the Study Area. In addition, a discussion of the hydrologic boundaries and hydraulic properties is also presented in this section.

Available hydrogeologic data were evaluated to define the groundwater flow system. Published data from the USGS, as well as site-specific investigation reports, were used to develop the hydrogeologic framework. Hydrogeologic characteristics including hydraulic conductivity, hydraulic gradients, porosity, and recharge were obtained from direct field measurements, where available, or interpreted from published information. Regional hydrogeologic features including areal extent and thickness of aquifers and bedrock topography were adopted from the USGS model. Groundwater levels within the Study Area were obtained from routine groundwater elevation monitoring at the Site between 2002 and 2003. The groundwater elevation data were then utilized for the calibration of the groundwater flow model. Groundwater extraction rates for the Kingsford and Iron Mountain municipal well fields were obtained from the USGS Model report.

DRAFT

2.1 Site Setting

The City of Kingsford is located in southwestern Dickinson County, in the south-central part of Michigan's Upper Peninsula (Figure 1). The City of Kingsford is bounded by the Menominee River on the west and south, by Breitung Township on the southeast, and by the City of Iron Mountain on the north and east.

The Site is located within a light industrial, commercial, and residential area of the City of Kingsford, and includes the former Plant site, the Northeast and Southwest pits, and the Riverside Disposal Area. The Study Area is primarily defined by the Menominee River to the west and south, Michigan State Highway 95 (Carpenter Avenue) to the east, and Woodward Avenue to the north. The Study Area is mostly within Sections 1, 2, 11, and 12 of Township 39 North, Range 31 West of Dickinson County. The Site and Study Area are presented in Figure 2.

DRAFT

2.1.1 Topography

The land surface immediately north of the City of Kingsford is dominated by Pine Mountain with an elevation over 1,500 feet above mean sea level (ft msl). South of Pine Mountain to Woodward Avenue in the City of Kingsford, the topography is irregular and contains numerous hills and hollows which are between 1,120 and 1,140 ft msl.

Three landform terraces dominate the topography, from Woodward Avenue south to the Menominee River. The uppermost terrace (Upper Terrace) consists of a large tract of land with a flat surface at an elevation of approximately 1,120 ft msl, which extends across most of the City of Kingsford. This terrace contains occasional isolated, enclosed depressions up to 40 feet deep that are glacial kettle landforms. These kettles are natural features formed by blocks of ice that broke off receding continental glaciers and subsequently melted. Several of the glacial kettle features have been filled in and are no longer visible in the topographic surface (NE and SW Pits).

The Upper Terrace is separated from a second terrace (Lower Terrace) by a steep northwest-southeast downward trending slope in the topography. The Lower Terrace occupies the southern and southwestern portions of the Study Area. The topography on the Lower Terrace is more irregular than the Upper Terrace, with the exception of the kettle features. From the Upper Terrace, the ground surface on the Lower Terrace slopes gradually downward to the south to approximately 1,080 ft msl, before rising gradually to an elevation of approximately 1,110 ft msl. The southern edge of the

Lower Terrace slopes steeply down to a third terrace (Riverside Terrace), which occurs along the banks of the Menominee River at an elevation of approximately 1,045 ft msl. The Riverside Terrace is found along the south and western sides of the City of Kingsford and Breitung Township. Further north and west, the Upper Terrace directly abuts the Menominee River.

2.2 Regional Geology

Precambrian metamorphosed igneous and sedimentary rocks make up the bedrock that underlies the City of Kingsford and Breitung Township (Milstein, 1987). Two bedrock formations are present in the area; the Lower Precambrian Quinnesec consisting of altered volcanic rocks, and the Middle Precambrian Michigamme Slate, consisting of primarily slate. A major east-west striking fault, downthrown to the north, has been documented by the USGS (Bayley, Dutton, and Lamey, 1966) to exist within the Study Area, south of the former Ford Plant. The fault separates the Quinnesec and Michigamme Formations, as well as Green Schist and Oligoclase-Amphibole regional metamorphic isofacies.

Bedrock is overlain by glacially derived unconsolidated deposits, except at locations south of the Ford Airport and close to the Menominee River, where bedrock is occasionally exposed. Examination of the bedrock outcrops reveal that apart from a few fractures, the bedrock is massive and therefore unlikely to transmit significant volumes of groundwater. The bedrock forms a depression beneath the central portion of the Study Area, with a monadnock located within the depression.

The unconsolidated deposits in the area include glacial moraines, present south (Menominee Moraine) and north (Marenisco Moraine) of the area (Westjohn et. al., 1996; Martin, 1995), and glaciofluvial (glacial river) deposits that form the uppermost glacial deposits in the area. These deposits may be pro-graded outwash that was deposited during formation of the Marenisco Moraine. A morphologic feature of the outwash is the presence of glacial kettles.

The unconsolidated deposits that overlie the bedrock consist of a complex sequence of interbedded gravel, sand, silt, and clay, with significant variations both vertically and laterally over short distances. These deposits are consistent with a glaciolacustrine (glacial lake) depositional environment. In some areas of the Study Area, a dense, silt/clay till unit, known as lodgement till, is present on top of the bedrock. Overall, coarser-grain deposits appear to be more abundant in the eastern part of the Study Area

DRAFT

and the unconsolidated deposits generally become increasingly finer-grain to the south and west.

Finer-grain silt and clay deposits are locally absent in some areas immediately adjacent to the banks of the Menominee River. In these areas, if bedrock is not exposed, a succession of gravel and coarse-grain to medium-grain sand rests on top of bedrock.

The principal soil in the Kingsford area is the Pence sandy loam (Soil Conservation Service [SCS], 1989). The unit is nearly level, well drained, and is typically found on flats and knolls in upland areas. The Channing fine sand loam and Zimmerman fine sand also occur along the Menominee River drainage ways and ridges, respectively (SCS, 1989).

DRAFT

2.3 Regional Hydrogeology and Hydrology

According to the USGS (Luukkonen and Westjohn, 2001), two regional glacial aquifers underlie the Kingsford and Iron Mountain area. The upper glacial aquifer comprising the upper terrace sand-and-gravel unit consists of 0 to 160 feet of medium to fine-grained sand with varying amount of silt and gravel. The lower outwash aquifer is comprised of approximately 0 to 240 feet of sand and gravel. The two aquifers are generally separated by a lacustrine silt and clay aquitard that ranges in thickness from 0 to 150 feet. The lithologic characteristics of the two aquifers vary locally with facies changes ranging from massive sand units to interbedded sands, gravels, and silt and clay. Similarly, the thickness and lithology of the confining bed is variable on a local scale, ranging from massive, stratified silt and clay beds to alternating beds of silt with fine sand.

The Menominee River is the principal hydrologic feature in the Kingsford area. The river flows to the southeast and forms the southern and western boundaries of the Study Area. Year-round flow and surface water level in the Menominee River is regulated by a number of dams, including a dam operated by Wisconsin Electric Power Company that is located northwest of the City of Kingsford (The Old Ford Dam) and the Big Quinnesec Dam downriver of the city. Apart from the Menominee River, no other surface water features are currently present south of Woodward Avenue.

In addition to Crystal Lake, there are a number of surface water features in the Kingsford area north and northeast of the city. Some of the lakes, such as Chapin Pit, are former iron mines that were subsequently abandoned and flooded.

The average precipitation in the Kingsford and Iron Mountain area is approximately 29 inches/year (NOAA Climate Database, 2004).

2.4 Site Hydrogeology and Stratigraphy

The Site hydrogeology is dominated by the glacial sediments. The town of Kingsford is located within a bedrock scallop feature and sediments are locally thickest within the Menominee River valley. Ongoing site investigation activities conducted by ARCADIS have identified four discreet water bearing zones within the unconsolidated glacial sediments adjacent to and on the east side of the Menominee River. From top to bottom these are referred to as the Zone A, Zone B, Zone C, and Zone D sands. Each of these units is generally separated from the underlying by a semi-confining unit that consists of silts, clays, and very fine-grained sands although in places the Zone B, Zone C, and/or Zone D sands may be in direct hydraulic connection with each other. The Study Area hydrogeology is depicted in cross-section parallel (north to south) and perpendicular (west to east) to the Menominee River in Figures 3 and 4, respectively. Figure 2 shows the location of the cross-sections depicted on Figures 3 and 4.

DRAFT

The physical characteristics of the unconsolidated glacial deposits (glaciofluvial and glaciolacustrine depositional environments) suggest that groundwater flowing beneath the Study Area follows irregular flow paths. Groundwater flow is in part controlled by the variable thickness and hydraulic conductivity of the saturated deposits. Saturated thickness is strongly influenced by bedrock topography and the water table configuration, both of which vary significantly beneath the Study Area.

Groundwater flowing through the unconsolidated deposits beneath the Kingsford area migrates to the Menominee River. Figure 5 shows the shallow aquifer groundwater flow pattern based on measurements obtained in June 2000. Due to its dense nature, the bedrock is the base of the groundwater flow in the overlying unconsolidated deposits. The hydraulic conductivity of the unconsolidated deposits is variable and corresponds to grain size. Finer-grain sand, silt, and clay have low hydraulic conductivities and hinder groundwater flow. In contrast, coarser-grain sand and gravel have higher hydraulic conductivity and allow groundwater to move more easily through them. The coarser-grain sand and gravel are preferential pathways for transmitting groundwater in the area.

Groundwater level measurements at paired wells indicate that a downward vertical component of the hydraulic gradient is present throughout most of the Study Area, except near the Menominee River where the vertical component of the hydraulic

gradient has always been observed as an upward flow condition. Except during unusual high water events, the groundwater would always vent into the Menominee River, because the pressure head of the groundwater is greater than the surface water of the Menominee River.

2.4.1 Zone A Sands

The Zone A sands correspond to the upper aquifer in the USGS model. The thickness of the Zone A sands range from approximately 40 feet, east of the Menominee River, to greater than 80 feet, west of the river and east of the upper terrace. East of the upper terrace, the Zone A sands consist primarily of massive fine- to medium grained sands with limited gravel content. West of the upper terrace, the sediments contain a higher fraction of medium to coarse sand with gravel and often include intervening silt or clay lenses. Based on the elevation of the top of the Zone A sands and the depth of the Menominee River, it appears that there are areas where the Menominee River channel might incise into the upper most water bearing unit. The Zone A sands are commonly encountered between approximately 1,010 ft msl and 1,080 ft msl.

The Zone A sands vary between confined and unconfined conditions, depending on the nature of the overlying sediments. Pumping tests performed during the siting of the Kingsford municipal wells, report an estimated transmissivity of between 9,100 and 11,400 feet squared per day (ft^2/day)(Luukkonen and Westjohn, 2001). Pumping tests performed by ARCADIS in the Zone A sands at Extraction Wells GMEW-1, GMEW-2, GMEW-5, and GMEW-6 ranged from approximately 600 to 4,700 ft^2/day (Appendix B).

2.4.2 Regional Confining Bed

Within the Study Area the regional confining bed consists primarily of fine sand and silt, with interbedded clay lenses, except beneath portions of the Menominee River where facies changes result in primarily fine sand. Where the confining unit consists of silt and clay (e.g., away from the Menominee River), there is a poor degree of hydraulic communication between the Zone A sands and the underlying Zone B and Zone C sands. However, beneath the Menominee River the occurrence of fine sand rather than silt or clay allow a greater degree of communication.

Pumping tests performed by ARCADIS in the Zone B and Zone C sands resulted in an range of estimated leakance (vertical hydraulic conductivity/layer thickness) for the confining beds of between 2.9×10^{-2} and 4.9×10^{-3} day^{-1} (Appendix B).

DRAFT

2.4.3 Zone B Sands

The Zone B sands occur between the regional confining bed and a much thinner confining bed (approximately 10 feet thick) immediately above the Zone C sands. This water bearing unit has been encountered along the Menominee River and appears to be laterally discontinuous. Where present along the river, the Zone B sands are often less than 20-feet thick and commonly contain intervening silt/clay beds. The Zone B sands have been observed between approximately 940 and 960 ft msl.

ARCADIS performed a pumping test at Extraction Well GMEW-4R. The estimated transmissivity for this test ranged between 334 ft^2/day for recovery and 602 ft^2/day during pumping.

2.4.4 Zone C and D Sands

Zone C and D sands correspond to the lower aquifer in the USGS model. The Zone C sands are laterally extensive with thickness ranging from approximately 60 to 80 feet; however, the morphologic characteristics vary from massive sands to interbedded sands with gravel and silt lenses. Throughout the majority of the study area the Zone C sands bottom on lodgement till or bedrock, except where the Zone D sands are present. The Zone D sands have been encountered adjacent to the Menominee River beneath a relatively thin silt/clay confining unit that underlies the Zone C sands. The morphology and lithology of the Zone D sands is similar to the Zone C sands, but are treated as a separate water bearing unit because groundwater impacts in these sands adjacent to the Menominee River have not been identified through prior investigations. The Zone C sands are encountered between approximately 860 and 940 ft msl. Where present adjacent to the Menominee River, the Zone D sands have been encountered at approximately 820 and 860 ft msl.

The USGS reported the pumping test results for the Kingsford and Iron Mountain wells in the lower aquifer and estimated transmissivity between 2,800 and 24,100 ft^2/day (Luukkonen and Westjohn, 2001). Pumping tests performed by ARCADIS at GMEW-3, GMEW-7, GMEW-8, and GMEW-9 resulted in an estimated range for transmissivity of the Zone C sands between approximately 1,770 and 3,100 ft^2/day (Appendix B).

DRAFT

3. Groundwater Flow Model Construction

ARCADIS used the simulation program MODFLOW 2000 to develop a numerical groundwater flow model for the Site. The primary phases in the development of a numerical groundwater flow model include the construction of a finite-difference grid for the model area, specification of model layer top and bottom elevations, assignment of boundary conditions, specification of hydraulic parameter values and zones, and selection of appropriate water-level measurements for calibration of the model. This information forms the basis for subsequent calibration of the numerical model to observed groundwater flow conditions in the Study Area.

D
R
A
F
T

3.1 Model Selection and Description

MODFLOW 2000 is a publicly available groundwater flow simulation program developed by the USGS (Harbaugh, Banta, Hill, and McDonald, 2000). The program is thoroughly documented, widely used by consultants, government agencies, and researchers, and is consistently accepted in regulatory and litigation proceedings.

In addition to its attributes of widespread use and acceptance, MODFLOW 2000 was also chosen because of its versatile simulation features. MODFLOW 2000 can simulate transient or steady-state saturated groundwater flow in one, two, or three dimensions and offers a variety of boundary conditions including specified head, areal recharge, injection or extraction wells, evapotranspiration, drains, and rivers or streams. Aquifers simulated by MODFLOW 2000 can be confined or unconfined, or convertible between confined and unconfined conditions. Regarding the hydrostratigraphy of the Site, which consists of a multi-layered geologic system with variable unit thicknesses and boundary conditions, MODFLOW 2000's three-dimensional capability and boundary condition versatility are essential for the proper simulation of groundwater flow conditions.

MODFLOW 2000 simulates transient, three-dimensional groundwater flow through porous media described by the following partial differential equation for a constant density fluid:

$$\frac{\partial}{\partial x}\left(K_{xx}\frac{\partial h}{\partial x}\right)+\frac{\partial}{\partial y}\left(K_{yy}\frac{\partial h}{\partial y}\right)+\frac{\partial}{\partial z}\left(K_{zz}\frac{\partial h}{\partial z}\right)-W=S_s\frac{\partial h}{\partial t} \qquad (3\text{-}1)$$

Where

> **K_{xx}**, **K_{yy}**, and **K_{zz}** are values of hydraulic conductivity along the x, y, and z coordinate axes, which are assumed to be parallel to the major axes of hydraulic conductivity [L/T];
>
> **h** is the potentiometric head [L];
>
> **W** is a volumetric flux per unit volume and represents sources and/or sinks of water [1/T];
>
> **S_s** is the specific storage of the porous material [1/L]; and
>
> **t** is time [T];

In Equation (3-1), the hydraulic parameters (i.e., K_{xx}, K_{yy}, K_{zz}, and S_s) may vary in space but not in time; the source/sink (W) terms may vary in both space and time.

MODFLOW 2000 uses a numerical approximation technique known as the method of finite differences to solve Equation 3-1 on a computer. Using a block-centered finite-difference approach, MODFLOW 2000 replaces the continuous system represented in Equation 3-1 by a set of discrete points in space and time. This process of discretization ultimately leads to a system of simultaneous linear algebraic equations. MODFLOW solves these finite-difference equations with one of the following four iterative solution techniques: strongly implicit procedure, slice-successive over-relaxation, preconditioned conjugate gradients, or LINK Algebraic Multigrid. The solution of the finite-difference equations produces time-varying values of head at each of the discrete points representing the real aquifer system. Given a sufficient number of discrete points, the simulated values of head yield close approximations of the head distributions given by exact analytical solutions to Equation 3-1.

The Department of Defense Groundwater Modeling System (GMS) software package, version 5.0, was used to pre- and post-process the MODFLOW 2000 simulation.

3.2 Model Discretization

The finite-difference technique employed in MODFLOW 2000 to simulate hydraulic head distributions in multi-aquifer systems requires areal and vertical discretization or subdivision of the continuous groundwater system into a set of discrete blocks that

DRAFT

form a three-dimensional model grid. In the block-centered finite-difference formulation used in MODFLOW 2000, the center of each grid block corresponds to a computational point or node. When MODFLOW 2000 solves the set of linear algebraic finite-difference equations for the complete set of blocks, the solution yields values of hydraulic head at each node in the three-dimensional grid.

Water levels computed for each block represent an average water level over the volume of the block. Thus, adequate discretization (e.g., a sufficiently fine grid) is required to resolve features of interest and yet not be computationally burdensome. MODFLOW 2000 allows the use of variable grid spacing so that a model may have a finer grid in areas of interest where greater accuracy is required and a coarser grid in areas requiring less detail.

DRAFT

The model domain and boundary conditions used for this model are generally the same as the USGS model. The exceptions include refinement of the grid spacing to allow analysis of groundwater extraction along the Menominee River and the addition of several model layers to provide more flexibility in simulating the stratigraphy identified at the Site.

The three-dimensional grid developed for the Site covers approximately 64 square miles (Figure 6). Except for the southern boundary, the boundaries of the model are located at distances from the area where the extraction system will be installed to minimize the effect of boundaries on model simulations of groundwater extraction. The southern boundary is defined as a no flow boundary to simulate the presence of near surface and bedrock outcropping in this area. The finite difference grid is composed of 704 rows and 343 columns with 8 vertical layers for a total of 1,931,776 nodes. The model uses 20 feet by 20 feet areal grid spacing in the vicinity of where the extraction system will be installed (along the Menominee River) to provide increased computational refinement for this area. This spacing increases to 500 feet by 1,000 feet at the limits of the active model domain. To avoid numerical and mass balance problems, adjacent cells were changed by no more than 50 percent.

The extent of the finite-difference grid and the areal grid spacing were selected for the purpose of simulating both regional groundwater flow conditions around the Study Area and detailed hydraulic head distributions in the vicinity of the proposed groundwater extraction system. The extent chosen for the grid also ensures adequate incorporation of regional groundwater flow features that could affect conditions at the proposed groundwater extraction system. The areal grid spacing specified within the Study Area allows for sufficiently detailed hydraulic heads to match water levels and groundwater

flow directions that have been measured. Meeting both of these objectives was needed for the calibration of the three-dimensional groundwater flow model.

The model was subdivided into eight layers to provide more flexibility in simulating the stratigraphy identified on Site. As the stratigraphy of the sedimentary units is reasonably flat, the model layer geometry was developed by contouring the bottom of the Zone A sands and using uniform thickness for the underlying water-bearing units and confining beds. The generalized conceptual model stratigraphy is shown on Figure 7. The vertical discretization of the model is summarized below:

D R A F T

- Layer one (top layer) was used to simulate the Zone A sands and overlying sediments. The top of layer one was derived from a digital elevation model for the Kingsford and Iron Mountain area.
- Layers two and three were used to simulate the regional confining bed and thicker portions of the Zone A sands.
- Layer four was used to simulate the Zone B sands and the thicker portions of the regional confining bed.
- Layer five was used to simulate the thin confining bed that separates the Zone B and Zone C sands.
- Layers six and seven were used to simulate The Zone C sands to account for the variability of the unit and underlying bedrock topography.
- Layer eight was used to simulate the Zone D sands and lodgement till.

Material property zonation was used within each of the layers as necessary to account for the fact that the top of bedrock extends above the groundwater table in the groundwater system comprising the glacial sediments.

3.3 Model Boundary Conditions

As indicated earlier, ARCADIS adopted the extent of the model domain and boundary conditions from the USGS model.

Boundary conditions are used to distinguish the area within the model domain from the adjacent groundwater system or hydrologic features. The boundaries of the model can

be specified several ways. They can occur at the edges of the model and at locations within the model domain where external features are represented, such as rivers, wells, and recharge. Boundary conditions at locations within the model domain typically relate to the simulation of natural recharge and stream channel recharge/discharge. This section presents a discussion of the boundary conditions simulated at the edges of the model domain.

Minor modifications to the USGS model boundary conditions were made in the model to account for site-specific data including staff gauge measurements in the Menominee River or elimination of constant head boundaries adjacent to the river or in deeper model layers. These modifications are identified in the sections that follow.

DRAFT

The external boundaries of the model are generally located at distances from the proposed groundwater extraction system to minimize the influence of the boundaries on the simulated groundwater flow patterns in this area. External model boundaries were chosen to coincide with natural surface-water discharge points or topographic ridges, which act as groundwater flow divides. The modeled area encompasses the lower portion of the drainage basins of the Brule and Little Popple Rivers, west of the Menominee River, and Lake Antoine to the north. The Study Area is bounded by topographic highs to the north and west. The western perimeter of the model is treated as a constant head boundary in model layer 1, using the prescribed heads from the USGS model. The Menominee and Brule Rivers constitute the southern perimeter of the model. The eastern boundary is the extension of the topographic highs from the north to the Menominee River at the southeastern corner, represented as a no-flow boundary. Where constant head or river boundaries are not prescribed, MODFLOW 2000 defaults to a no-flow boundary. This is the condition beneath the bottom of the model and along the northern and eastern perimeter.

Figure 8 shows the plan view map of the model domain and the assigned boundary types. Constant head boundaries are shown on Figure 8 using orange squares.

3.3.1 River Boundary Conditions

The Menominee River, Brule River, Little Popple Creek, Lake Antoine, Crystal Lake, Cowboy Lake, and two mine shafts were simulated using the river package in MODFLOW 2000. The location of the river boundaries are shown on Figure 8 using blue crosses.

The interaction between the surface water bodies and groundwater system is simulated as a function of the head difference between the water table and the surface water, as well as the degree of hydraulic communication. River boundaries simulate the interaction with the uppermost hydrostratigraphic unit through the specification of a surface-water stage, bed elevation, and a conductance term. River boundaries allow groundwater to flow from or to the aquifer, based on the difference between the stage and simulated water level (head) in the groundwater system. If the simulated water level in the groundwater system is below the stage elevation, the river cell recharges water into the groundwater system based on the bed conductance. If the stage in the surface water body is lower than the groundwater system, groundwater flows in to the surface water body (river cell).

The stages and bed elevations for the surface water bodies were based on USGS topographic maps, dam elevations, and staff gauge measurements during the interval for calibration. The conductance terms for the river cells were calculated from the individual grid cell dimensions and the calibrated hydraulic conductivity of the groundwater system, assuming a unit bed thickness.

D
R
A
F
T

3.3.2 Kingsford and Iron Mountain Municipal Wells

Pumping at the Kingsford and Iron Mountain well fields was simulated using the well package in MODFLOW 2000. Use of the well package requires specification of well screen interval and average pumping rate (for steady-state simulation) during the period of interest. ARCADIS used the pumping rate information from the USGS model. Table 1 summarizes the average flow rates used for the municipal wells that were simulated in the model during calibration and identifies which model layer is being pumped.

After model calibration, ARCADIS used the well package to simulate pumping from groundwater extraction wells along the Menominee River in the Zone A, Zone B, and Zone C sands. The flow rates and well construction for these simulations are discussed in Section 5.

3.3.3 Recharge

Recharge (percolation of infiltrating precipitation) was applied to the uppermost active model layer (layer 1). Net areal recharge from precipitation within the Study Area was the primary source of inflow to the model. The net recharge is defined as the total recharge from precipitation and re-infiltrated runoff that is available to the water-table

after taking into account loses from evapotranspiration and surface-water runoff. Estimates of recharge were obtained from the previous modeling efforts and published climatic data. The USGS model used average discharge data from gauging stations to estimate the upper limit of recharge, as it represents base flow (groundwater contributions) and surface water run-off. According to the data cited in their report, during the period between 1996 and 1997, the average annual discharge in the Menominee River at Niagara, Wisconsin was 13.8 inches per year. The USGS model assumed that recharge rates were zero, where bedrock and till outcrop at the surface, and 9 inches per year throughout the rest of their model.

ARCADIS used a similar recharge zonation scheme in this model, except that the bedrock and till areas received a minor amount of recharge. The calibrated estimate of annual recharge was 9 inches per year (2.1×10^{-3} feet per day) across the areas that did not exhibit bedrock or till at the ground surface and 0.2 inches per year (5.0×10^{-5} feet per day) at the bedrock and till locations. The recharge zonation for the calibrated model is shown on Figure 9.

3.4 Hydraulic Parameters

ARCADIS used the results of pumping tests to parameterize the region of the model in the vicinity of the proposed groundwater extraction system. For the external areas, ARCADIS maintained the initial estimates of the hydraulic conductivity that were developed in the USGS model.

Initial estimates of horizontal and vertical hydraulic conductivity in the individual model layers were developed using the transmissivity and leakance values from the corresponding pumping tests in the Zone A, Zone B, and Zone C sands. The areal extent of the individual hydrostratigraphic units and confining beds were mapped using the boring logs, cross-sections, geologic visualization, and bedrock topography previously developed during the site investigation. During the calibration process, parameter values were adjusted up or down as necessary to improve the match between the simulated and observed heads. Throughout the process, the parameter values were compared with the site-specific pumping test results to ensure that the model assumptions regarding horizontal and vertical hydraulic conductivity (leakance) were consistent. During the process, it was recognized that the variability of the morphology and lithology within the water-bearing units and confining beds was significant. Therefore, the hydraulic parameters were prescribed using zones to account for the influence of the depositional environment on the hydraulic behavior and to map the 3-dimensional nature of the bedrock.

DRAFT

The resulting assemblage of model assumptions is deemed an accurate representation for the available information and resources of the hydrogeologic system at the Site and will allow confident use of the model to evaluate groundwater pumping requirements to prevent discharge of groundwater exceeding acute GSI criteria to the Menominee River.

3.4.1 Model Hydraulic Parameter Zonation

Once the extent of the individual stratigraphic units was mapped to the individual model layers, ARCADIS reviewed the morphological and lithological trends within each unit to develop facies maps for the sediments using polygons in the GMS system. The area included within each polygon was determined based on review of morphologic characteristics (i.e., massive sand, graded sands, or interbedded sands and silts) and lithologic trends (percent gravel, sand, fine materials within the water bearing units or confining beds). After grouping similar facies, effective horizontal and vertical hydraulic conductivity values were calculated and mapped to the MODFLOW model for simulation and evaluation. The areal and vertical extents of bedrock were also mapped in this fashion

The final hydraulic parameters for the calibrated model zonation for each layer is summarized in Table 2 and presented in plan view on Figures 10 through 17. Throughout the model layers, bedrock was treated using a single value for horizontal hydraulic conductivity (0.001 feet/day) and vertical hydraulic conductivity (0.0001 feet/day).

In general, vertical anisotropy (e.g., ratio of horizontal to vertical hydraulic conductivity) within the sand units was varied between approximately 10 and 15 for less stratified morphologies and between 120 and 390 for interbedded morphologies. Horizontal hydraulic conductivity for the water bearing units ranged between approximately 20 and 32 feet per day for fine sand to silty sand to approximately 160 feet per day for sand and gravel mixtures.

The horizontal hydraulic conductivity of the confining beds ranged from 0.01 feet per day for interbedded silt and clay to approximately 5 feet per day for silt or sandy silt. The vertical anisotropy for the confining beds ranged from approximately 120 to 1,200.

DRAFT

3.5 Calibration Targets

Calibration targets are a set of field measurements, typically groundwater elevations, used to test the ability of a model to reproduce observed conditions within a groundwater flow system. For the calibration of a steady-state (time-invariant) model, the goal in selecting calibration targets is to define a set of water-level measurements that represent the average elevation of the water-table or potentiometric surface at locations throughout the model domain.

Table 3 lists the monitoring wells and water-level elevations chosen for the calibration of the groundwater flow model. This list of calibration targets represents water-level elevations measured between January 2002 and December 2003. The model calibration targets were selected to provide groundwater levels within each of the Zone A, Zone B, Zone C, and Zone D sands. Monitoring wells under the influence of the vapor extraction system, groundwater extraction wells, or gas-phase methane were specifically excluded from the target list. There are a total of 92 calibration targets. There are 53, 13, 17, and 9 calibration targets in Zone A sands (model layers 1 and 2), Zone B sands (model layer 4), Zone C sands (model layers 6 and 7), and Zone D sands (model layer 8), respectively. The locations of the calibration targets are shown on the calibrated groundwater flow maps for Zone A, Zone B, Zone C, and Zone D sands in Figures 19 through 23.

DRAFT

4. Groundwater Flow Model Calibration

Calibration of a groundwater flow model refers to the process of adjusting model parameters to obtain a reasonable match between observed and simulated water levels. In general, model calibration is an iterative procedure that involves variation of hydraulic properties or boundary conditions to achieve the best match between observed and simulated water levels. During model calibration, site-specific pumping test data were used as the primary constraints for the calibrated values of hydraulic conductivity based on the greater reliability of the data.

DRAFT

4.1 Calibration Procedure

For best results, the calibration of a model should rely on discrete measurements to produce answers free of contouring interpretations. In the calibration of a groundwater flow model, use of point data eliminates the potential for interpretive bias that may result from attempting to match a contoured potentiometric surface (Anderson and Woessner, 1992). The groundwater flow model for the Site was calibrated using 92 water-level calibration targets measured in monitoring wells distributed throughout the hydrogeologic units identified (see Table 3).

As a further goal for the calibration of a model, the principle of parameter parsimony is applied to achieve an adequate calibration of the model through the use of the fewest number of model parameters. It should be noted that the use of greater numbers of model parameters during model calibration creates a situation in which different combinations of model parameter values produce similar calibration results. In this case, the model calibration parameters are called non-unique. Following the principle of parameter parsimony reduces the degree of non-uniqueness and results in more reliable calibrated parameter values. The information gathered for the conceptual model guides any decision to add model parameters (e.g., zones of hydraulic conductivity) to the model during the calibration process. Therefore, in the absence of hydrogeologic evidence, the simpler model is preferred.

During the calibration procedure initial estimates for the model parameters are systematically varied to minimize the difference between simulated and observed water levels at a set of calibration targets. Model parameters were adjusted in a systematic manner until a reasonable fit was obtained between the model solution and the target water-elevation data.

The primary criterion for evaluating the calibration of a groundwater flow model is the difference between simulated and observed water levels (heads) at a set of calibration targets. A residual or model error, e_i, is defined as the difference between the observed and simulated hydraulic head measured at a target location:

$$e_i = h_i - \hat{h}_i \quad (4\text{-}1)$$

where h_i is the measured value of hydraulic head and $\hat{h}_i$ is the simulated value at a specific target location. A residual with a negative sign indicates overprediction by the model (i.e., the simulated head is higher than the measured value). Conversely, a positive residual indicates underprediction.

The automatic parameter estimation procedure seeks to minimize an objective function defined by the residual sum of squares (RSS):

$$RSS = \sum_{i=1}^{n} \left(h_i - \hat{h}_i\right)^2 \quad (4\text{-}2)$$

where n is the total number of calibration targets.

The root mean square error (RMSE), which normalizes the RSS by the number of calibration targets, is defined as follows:

$$RMSE = \sqrt{\frac{RSS}{n}} \quad (4\text{-}3)$$

The RSME is useful for comparing model calibrations because it is normalized by the number of calibration targets and thus provides a measure of the average RSS error associated with each point. The RMSE is the primary measure of calibration used in this report. Another calibration measure is the mean of all residuals, or mean error (ME):

$$ME = \frac{1}{n} \sum_{i=1}^{n} e_i \quad (4\text{-}4)$$

DRAFT

A mean residual significantly different from zero indicates model bias. Lastly, the mean average error (MAE) provides an indication of the magnitude of the mean error as shown below:

$$MAE = \frac{1}{n}\sum_{i=1}^{n} / e_i / \qquad (4\text{-}5)$$

4.2 Calibration Results

The groundwater flow model calibration required numerous individual computer simulations. The values and shapes of the various parameter zones in the model were gradually varied until a reasonable solution was achieved in agreement with the conceptual model. The 92 water-level targets selected for the calibration of the groundwater flow model were used to evaluate the calibration of the model through the analysis of (1) simulated hydraulic head distributions in the model layers, (2) residual statistics, and (3) estimated hydraulic parameters.

4.2.1 Simulated Hydraulic Head Distribution

As a part of evaluating the calibration of the numerical model, simulated potentiometric surface maps are prepared for each of the water-bearing unit model layers to depict groundwater flow conditions in the Zone A, Zone B, and Zone C sands. The regional (model-wide) simulated groundwater flow pattern for model layer one is shown on Figure 18. Figures 19 and 20 show the calibrated groundwater flow patterns and residuals associated with the Zone A sands in model layer one and two, respectively. Figure 21 shows the calibrated groundwater flow patterns for the Zone B sands in model layer four. The calibrated groundwater flow patterns for the Zone C sands (model layers six and seven) and Zone D sands (model layer eight) are shown in Figures 22 through 24, respectively. Figure 25 depicts groundwater flow in cross-section from the area near the northeast pit to the Menominee River.

From the simulated groundwater contours in the aquifer units (Figures 19 through 24), it is apparent that in the vicinity of the proposed groundwater extraction system groundwater flows primarily to the west toward the Menominee River. This result is in general agreement with prior groundwater flow interpretations and is consistent with the distribution of groundwater impacts identified at the Site. Review of the groundwater flow in cross-section indicates that flow originating near the Northeast pit is generally downward (consistent with local recharge) to the Zone C sands and then horizontal toward the Menominee River, where flow is directed upward to the point of

DRAFT

discharge. This flow pattern in cross-section is also consistent with the lateral and vertical distribution of groundwater impacts, which indicates that the shallow portion of the groundwater system (Zone A sands) exhibits significantly less impacts in the area between the Northeast pit and the Menominee River.

4.2.2 Analysis of Residuals

The calibration of the groundwater flow model for the Study Area sought to minimize the RMS error (Equation 4-3) computed for the 92 water-level calibration targets. Table 4 lists the simulated water elevations and model residuals for each of the calibration targets. The maps of simulated hydraulic heads (Figure 18 through 23) show the spatial distribution of these residuals in the Zone A, Zone B, and Zone C sands, respectively..

The largest computed residual for the entire set of targets is 16.67 feet. Approximately 90 percent of the targets have residuals of 5.0 feet or less. Overall, the model shows a good match to the measured water levels in the Study Area. Figure 26 shows graphically the agreement between observed and simulated water levels (heads) at the calibration targets. As shown on Figure 26, six target points fall outside the plus/minus 10-precent range of observed heads, which was 65 feet.

Residual statistics (summarized on Figure 26) for the calibrated groundwater flow model indicate good agreement between simulated and measured groundwater elevations. The calculated RMS error for the calibrated model was 3.41, which is approximately 5 percent of the 65-foot range of observed heads for the entire model domain. The calculated residual ME, -0.37 feet, is close to zero indicating limited bias. The MAE was calculated to be 2.30 feet. These statistics show that a high level of calibration standard has been achieved in this modeling effort and overall, the model shows a very good match to the measured water levels in the Study Area.

4.2.3 Model Flow Balance

The calibrated model solution was obtained with virtually no flow balance error (see Table 5). Evaluation of the calibrated model flow budget summarized on Table 5 indicates that the majority of the water input into the model (approximately 53 percent) is derived from recharge. Constant head boundaries also contributed a significant portion of inflow (40 percent), with river cells contributing the least (approximately 7 percent). Note that river cells were used to simulate the lakes (Lake Antoine, Crystal Lake, and Cowboy Lake) and mine shafts, as well as the Menominee River, Brule

DRAFT

River, and Little Popple River in the model. The majority of the inflow (greater than 90 percent) is due to the lakes that are simulated using the river cells. The majority of the outflow from the model is through leakage to the river boundaries, particularly to the Menominee River.

4.2.3.1 Sensitivity Analysis

4.2.4 Methods of Analysis

D R A F T

Once the model was calibrated, a sensitivity analysis was performed to identify which model input parameters have the most impact on the degree of calibration. The model sensitivity analysis was conducted in general accordance with the procedures presented in American Society for Testing and Materials (ASTM) Standard D 5447 Application of a Ground-Water Flow Model to a Site-Specific Problem (ASTM, 1994).

Sensitivity analysis was performed to examine the effects of uncertainties in each of the model calibration parameters. The response of the calibrated model (as indicated by the RMSE) to changes in the horizontal hydraulic conductivity, vertical hydraulic conductivity, river bed conductance, and recharge in the study area was evaluated through a discrete sensitivity analysis. In this analysis, one parameter at a time was varied while all other parameters were held constant. For horizontal conductivity, the parameter values within the model layers and zones corresponding to the Zone A, Zone B, Zone C, and Zone D sands were varied at the same time using a multiplier on the calibrated model values. Similarly, vertical conductivity of the aquitard (confining beds) layers and zones were varied by the same factor for each sensitivity run. Riverbed conductance values were varied only within the vicinity of the proposed groundwater extraction system, while recharge parameters were varied across the model domain.

To quantify parameter sensitivity, each calibrated parameter was initially varied by a factor of plus or minus 20 percent (e.g., multiplied by a factor 1.2 and 0.8). A normalized RMSE was then calculated for the revised values by dividing the resulting RMSE by the value for the calibrated model (3.41) and multiplying by 100. The range of parameter variation for each parameter's sensitivity analysis was determined based on the magnitude of change in the normalized RMSE and model stability. The latter criterion, model stability, was assessed by evaluating mass balance errors and the number of dry cells, which could make the model unreliable or unrepresentative. The former criterion, change in normalized RMSE, was quantitatively evaluated for each sensitivity simulation that converged without significant mass balance error or dry

cells. A model is characterized as being "insensitive" to a model parameter when the magnitude of change in the normalized RMSE is less than the change in the parameter. Conversely, a model is termed "sensitive" or "highly sensitive" to a parameter when the change in the magnitude of the normalized RMSE error is greater or much greater than the change in the parameter. Therefore, the range of each parameter variation was determined by the model sensitivity. The results of the sensitivity analysis are discussed in the sections that follow.

DRAFT

4.2.4.1 Horizontal Hydraulic Conductivity

The hydraulic conductivity values in each aquifer matrix zone for all layers except layer 3 (regional confining bed) were multiplied by 0.5, 0.8, 1.2, and 1.5. The resulting RMS errors are summarized in Table 6 and graphed on Figure 27. Based on the relative change in computed RMS errors for these sensitivity simulations, it appears that the model is relatively insensitive to minor changes in horizontal hydraulic conductivity, as increasing or decreasing hydraulic conductivity by 20 percent results in a change in RMSE of approximately 3 percent. In response to a 50-percent increase in hydraulic conductivity, the RMSE increased only 10-percent; however, at a decrease of 50-percent, the RMSE increased nearly 40 percent, which is the largest observed change in RMSE for the sensitivity analysis. These results indicate that model is sensitive to a reduction in hydraulic conductivity, but relatively insensitive to modest increases.

As shown on Figure 27, the calibrated model is located at the local minimum RMSE, indicating that the calibrated model estimates of hydraulic conductivity provide the best overall results.

4.2.4.2 Vertical Hydraulic Conductivity (Leakance)

The vertical hydraulic conductivity (leakance) values for the aquitard units in all layers except for layer 8 were multiplied by 0.5, 0.5, 1.2, and 1.5 to evaluate the calibrated model's sensitivity to this parameter. The resulting normalized RMSE (see Table 6) are graphed on Figure 27. As shown in Table 6 and on Figure 27, the model is insensitive to increases and decreases in vertical hydraulic conductivity for the aquitard matrix with resulting increases of approximately 5 and 11 percent in RMSE when values are decreased or increased by a range of 50 percent.

The low degree of change in the RMSE with changes in vertical hydraulic conductivity indicates that the model is insensitive to range of values considered in the sensitivity

analysis. Given the very small relative changes in RMSE as a result of a wide range of this parameter, it is unlikely that a significant improvement in the model can be achieved by considering a wider range of parameter values. While a larger range of vertical conductivity could be evaluated, this would result in model leakance values that would be inconsistent with the results of the pumping tests near the Menominee River.

4.2.4.3 Recharge

Areally distributed recharge (infiltrating precipitation) is the primary source of water in the groundwater flow model. The areally distributed recharge rates used in the calibrated model (see Figure 9) were multiplied by a factor of 0.8, 0.9, 1.1, and 1.2 to evaluate the model's sensitivity to recharge. The results are summarized in Table 6 and plotted on Figure 27.

As shown on Figure 27, the model is somewhat sensitive to the amount of recharge. Relatively minor decreases in the recharge rate result in a proportional increase in RMSE. The model is less sensitive to increasing recharge rates, in fact, a 10 percent increase in the recharge rate resulted in almost no change in the RMSE. However, an increase of 20 percent in recharge results in a more proportional increase in RMSE. Recharge appears to be the most sensitive parameter in the model.

4.2.4.4 River Bed Conductance

The Menominee River is the primary outlet for groundwater in the model. The calibrated model river conductance values were multiplied by 0.5, 0.8, 1.2, and 1.5. As shown in Table 6 and on Figure 27, the resulting changes in RMSE were minor with changes of 50 percent resulting in an RMSE change of 8 and 2 percent. The river conductance appears to be the least sensitive parameter in the model.

4.2.5 Summary of Sensitivity Analysis Results

Results of the sensitivity analysis indicate that the model is relatively insensitive to variations in vertical hydraulic conductivity and river conductance over a plus/minus 50-percent range of the calibrated model values. The sensitivity analysis results indicate that horizontal hydraulic conductivity is slightly more sensitive to change with the greatest influence occurring with a substantive decrease. The most significant model sensitivity is recharge. Because recharge is a sensitive parameter, the quality of information used to determine it is important. Recharge for the aquifer was based on

D R A F T

the rate used by the USGS model with a comparison to actual Site precipitation data which indicates that it is appropriate. It is believed that recharge is defined adequately for the intent of the modeling effort.

DRAFT

5. Groundwater Pumping Simulations

ARCADIS used the calibrated groundwater flow model in conjunction with simulated pumping to evaluate the configuration and flow rates of extraction wells in the Zone A, Zone B, and Zone C sands to capture a plume of groundwater that exceeds MDEQ acute GSI criteria adjacent to the Menominee River. The rationale for the definition of the reaches along the Menominee River requiring capture is presented in the ARCADIS document "*Hydrogeologic Framework, Areas Exceeding Acute GSI Criteria, and Results of Aquifer Pumping Tests Performed in the Vicinity of the Menominee River*", which is included in Appendix B.

D R A F T

Groundwater flow and particle tracking simulations, using MODPATH (Pollack, 1994), were performed to aid in the design of the groundwater extraction system. Based on the analysis presented in Appendix B, the following areas adjacent to the Menominee River in the Zone A, Zone B, and Zone C sands exceed the acute GSI criteria and were targeted for the evaluation:

- Zone A sands – between Monitoring Wells GM-78 and GM-79.
- Zone B sands – between Soil Borings GMSB-112 and GMSB-113.
- Zone B sands – between Monitoring Wells GM-66A/B and GMSB-63A/B.
- Zone D sands – there are no exceedances of acute GSI criteria.

Numerous groundwater flow and particle tracking simulations were performed to evaluate the optimal configuration of the extraction well arrays and to determine the pumping rates required to maintain capture of the plume in the target areas. There were two constraints that were used to guide the evaluation of the capture zone analysis:

- The draft Consent Judgment requires that an inward hydraulic gradient (in permeable zones) be maintained continuously where groundwater exceeds (acute) GSI criteria at a maximum distance of 70 feet landward from the ordinary high water mark in the Menominee River. For purposes of this analysis, it was assumed that if an extraction well ceased pumping, the pumping rate on the adjacent pumping wells (within that same zone) would have the capability of being

increased by 50 percent and at that rate the system would be capable of maintaining the inward gradient. In other words, under average pumping conditions each well is pumped a minimum of 2/3 of its maximum rate so that if an adjacent well (within the same zone) ceases operation the adjacent wells pumping rates can be increased by 50 percent.

§ The pumping rates used in the scenarios were based on a consideration of the hydraulic capabilities of the permeable zones being pumped (well yield) and engineering constraints on the range of pumping rates provided by available pumps. For example, our experience with existing Extraction Well GMEW-2 suggests the maximum rate for pumping a well screened in the Zone A sands is 15 gallons per minute (gpm), due to the hydraulic properties of the Zone A sands and the limited available drawdown. The grundfos pump (the brand of pump to be used in the extraction system) that provides this pumping rate is Model # 16S, which has the flexibility to pump within the range of 10 to 20 gpm. The simulations performed for the Zone A sands are based on pumping every well at 10 gpm. For the Zone C sands, the maximum pumpage rate was assumed to be 30 gpm. The simulations performed for the Zone C sands are based on pumping every well at 20 gpm (Model #25S pumps between 18 and 32 gpm). For Zone B sands, the maximum pumping rate is assumed to be 15 gpm and the simulations for the Zone B sands assumed a pumping rate of 10 gpm.

DRAFT

Two scenarios considering different off-set distances from the Menominee River were evaluated to assess the optimal well spacing and flow rates necessary to meet the requirements for capture subject to the practical engineering constraints described above.

§ Scenario One: Pumping wells off-set 70 feet from, and parallel to Menominee River (e.g., on a line 70-foot from the river) except on the southern end of the extraction system at the location of the treatment plant.

§ Scenario Two: Pumping wells off-set up to a maximum of 350 feet from Menominee River, where space is available

The results of the evaluation for each of the two scenarios are presented in the sections that follow.

5.1 Particle Tracking Simulations

Particle tracking simulations were used to assess capture of the plume in the two areas described above. The primary objectives were to ensure capture of the upgradient plume exceeding acute GSI criteria while creating a downgradient stagnation zone (due to pumping) that would be located, on average 70 feet or less from the ordinary high water level of the Menominee River.

Particles were placed in cells between the Menominee River and a north-south line approximately 350 feet from the river (e.g., Scenario Two pumping well locations) to assess the downgradient capture and stagnation zone location in the Zone A, Zone B, and Zone C sands.

By convention, the starting location of each particle is shown with green dots and the ending location is shown using orange dots. The lines between the dots indicate the path of the groundwater flow under conditions of advective transport only.

For the particle tracking analysis, the porosity of the Zone A, Zone B, and Zone C sands was assumed to be 30 percent.

5.1.1 Scenario One – Pumping Wells Placed 70 Feet from Menominee River

Scenario 1 is the most conservative scenario modeled since the extraction well arrays for each of the sands parallel the river and are located at a distance of 70 feet from the river. The advantage of this approach is that the stagnation zone would be located at a distance that is less than 70 feet from the river, provided that the pumping is adequate to capture flow between the individual wells.

There are 23 wells in the Zone A sands spaced approximately 80 feet apart, except at the northern end of the well network, where the wells are spaced approximately 60 feet apart. There are three wells in the Zone B sands spaced at approximately 160 feet and 11 wells in the Zone C sands spaced at approximately 200 feet apart. The pumping rates for the wells in the Zone A, Zone B, and Zone C sands are 10, 10, and 20 gpm, respectively.

Figures 28, 29, and 30 show the results for the Zone A, Zone B , and Zone C sands, respectively for Scenario One. These figures show the extraction well network is capable of capturing upgradient groundwater exceeding acute GSI criteria in each of the target areas in Zone A, Zone B, and Zone C sands, respectively, as none of the

DRAFT

particles upgradient of the seventy-foot line escape the extraction well network. The total extraction rate for this scenario is 480 gpm (Zone A sands, 230 gpm; Zone B sands, 30 gpm; & Zone C sands, 220 gpm).

Comparison of the flow balance and budget with the calibrated model (see Table 7) indicates that the groundwater discharge to the river under Scenario One is reduced by 90,270 cubic feet per day (cfd) or approximately 470 gpm. Net leakage from the river increased by approximately 2,048 cfd (approximately 10 gpm), which combined with the decreased discharge makes up the combined pumping rate of 480 gpm. This minor increase in river leakage due to pumpage indicates that the pumping wells would create a minor flow reversal from the Menominee River.

DRAFT

5.1.2 Scenario Two – Pumping Wells Placed up to 350 Feet from Menominee River

Scenario 2 was considered to evaluate the capture performance at a greater distance from the river where possible, to minimize flow contributions from the river. Wells in the Zone C sands on the northern end of the extraction system would parallel the river at a distance of about 70 feet along the inside of the narrow corridor between the river and the steep bluff. South of the corridor the wells in all three sand zones would be located primarily in a north-south line that passes through existing Extraction Well GMEW-8 (which would be used as one of the extraction wells) and intersects with the southern wells in the Zone A sands extraction well array, near the treatment plant.

There are 21 wells in the Zone A sands spaced approximately 80 feet apart, except at the northern end of the well network, where the wells are spaced approximately 60 feet apart. There are three wells in the Zone B sands spaced at approximately 160 feet and 10 wells in the Zone C sands spaced at approximately 200 feet apart. The pumping rate for the wells in the Zone A, Zone B, and Zone C sands are 10, 10, and 20 gpm, respectively.

Figures 31, 32, and 33 show the results for the Zone A, Zone B, and Zone C sands, respectively, for Scenario Two. As shown, the extraction wells capture the particles placed between the pumping wells and the seventy-foot line from the river, which indicates that the stagnation zone is seventy feet or less from the river. The total extraction rate for this scenario is 440 gpm (Zone A sands, 210 gpm; Zone B sands, 30 gpm; and Zone C sands, 200 gpm).

Comparison of the Scenario Two flow balance and budget with Scenario One (see Table 7) indicates that discharge to the river increased by approximately 5,703 cfd (30

gpm), which is essentially the difference between pumping rates in the two scenarios. River leakage into the model does not significantly change between the two pumping scenarios, indicating that locating the wells further from the river as in Scenario Two would still result in a minor flow contribution from the Menominee River.

6. Conclusions and Recommendations

6.1 Conclusions

D R A F T

Based upon the development of the conceptual model, construction of the three-dimensional finite-difference model, calibration, sensitivity analysis, and model simulation, the following conclusions are presented:

- The conceptual model properly characterizes salient features of the Ford/Kingsford Site including bedrock surface topography, groundwater levels, boundary conditions, groundwater pumping locations and rates, and groundwater/surface-water interaction.

- The calibrated model adequately captures the major features of the groundwater flow system. The elevation, shape, magnitude, gradient, and position of the potentiometric surface are comparable to that simulated by the calibrated model.

- The calibration of the groundwater flow model for the Study Area sought to minimize the RMSE computed for the water-level calibration targets. Evaluation of the residual statistics indicates that the model is accurately calibrated to the Study Area targets. Overall, the model shows a good match to the measured water levels in the Study Area. All but six residuals fall within the 10 percent range of observed water-level elevations (65-foot difference in observed water levels) with 90 percent of the targets having residuals of 5.0 feet or less. In ARCADIS' opinion, the groundwater flow model accurately reflects the hydrogeologic conditions in the Study Area and can be used to evaluate groundwater flow conditions.

- The results of the sensitivity analysis indicate that the calibrated model provides the best overall selection of model parameters to describe the site-wide behavior of the groundwater system. Significant reduction in model errors could not be accomplished over the range of hydraulic conductivity, recharge, and river bed conductances considered. The sensitivity analysis indicates that the groundwater model is most sensitive to changes in recharge and horizontal hydraulic

conductivity. Lesser sensitivity was demonstrated with respect to vertical conductivity (leakance) and river bed conductance.

§ Results of the simulated groundwater extraction indicate that groundwater flow in the Zone A, Zone B, and Zone C sands can be controlled to capture groundwater that exceeds acute GSI criteria adjacent to the Menominee River under the conditions of Scenarios One or Two. A slightly higher flow rate (480 gpm) is required if the extraction wells are arrayed at the seventy-foot line (Scenario One) than if the well arrays are set back (440 gpm for Scenario Two).

6.2 Recommendations

It is anticipated that the groundwater model will be utilized on an ongoing basis to assist in the evaluation of the performance of the groundwater extraction system.

The groundwater model can be used with confidence to aid in establishing the number and location of hydraulic monitoring points necessary to verify capture performance.

Additional data acquired during the operation of the groundwater extraction system can be used to refine the existing model and assist in evaluating and optimizing on-going performance.

Ground-Water Flow and Contributing Areas to Public –Supply Wells in Kingsford and Iron Mountain, Michigan

ABSTRACT

The cities of Kingsford and Iron Mountain are in the southwestern part of Dickinson County in the Upper Peninsula of Michigan. Residents and businesses in these cites rely primarily on ground water from aquifers in glacial deposits. Glacial deposits generally consist of an upper terrace sand-and-gravel unit and a lower outwash sand-and-gravel unit, separated by lacustrine silt and clay and eolian silt layers. These units are not regionally continuous, and are absent in some areas. Glacial deposits overlie Precambrian bedrock units that are generally impermeable. Precambrian bedrock consists of metasedimentary (Michigamme Slate, Vulcan Iron Formation, and Randville Dolomite) and metavolcanic (Badwater Greenstone and Quinnesec Formation) rocks. Where glacial deposits are too thin to compose an aquifer usable for public or residential water supply, Precambrian bedrock is relied upon for water supply. Typically a few hundred feet of bedrock must be open to a wellbore to provide adequate water for domestic users. Ground-water flow in the glacial deposits is primarily toward the Menominee River and follows the direction of the regional topographic slope and the bedrock surface.

To protect the quality of ground water, Kingsford and Iron Mountain are developing Wellhead Protection Plans to delineate areas that contribute water to public-supply wells. Because of the complexity of hydrogeology in this area and historical land-use practices, a steady-state ground-water-flow model was prepared to represent the ground-water-flow system and to delineate contributing areas to public-supply wells. Results of steady-state simulations indicate close agreement between simulated and observed water levels and between water flowing into and out of the model area. The 10-year contributing areas for Kingsford's public-supply wells encompass about 0.11 square miles and consist of elongated areas to the east of the well fields. The 10-year contributing areas for Iron Mountain's public-supply wells encompass about 0.09 square miles and consist of elongate areas to the east of the well field.

INTRODUCTION

In 1997, the U.S. Geological Survey, in cooperation with the cities of Kingsford and Iron Mountain, began a 2-year study to describe ground-water flow and determine the areas that contribute water to the cities' public-supply wells. The cities of Kingsford and Iron Mountain are in the southwestern part of Dickinson County, in the Upper Peninsula of Michigan (fig. 1). Both of these cities currently have four municipal wells in glacial aquifers that provide ground water to residents and businesses for water supply (fig. 2). In an effort to protect the quality of ground water that is withdrawn by these wells, the cities of Kingsford and Iron Mountain are developing Wellhead Protection Plans (WHPP). As part of WHPP, the cities will delineate areas that contribute water to public-supply wells. Kingsford's wells are located near Cowboy Lake and near Ford Airport (fig. 2). Iron Mountain's wells are located about 2 miles north of Kingsford's well fields. Because of the complexity of hydrogeology in these areas and historical land-use practices, a computer model is needed to describe the ground-water-flow system and to delineate areas that contribute water to public-supply wells.

This report describes the hydrology of the Kingsford-Iron Mountain area and the simulation of ground-water flow in the Kingsford-Iron Mountain area. During this study, water levels were measured in 28 domestic, irrigation, and observation wells to determine ground-water-flow directions. Thirteen aquifer tests performed previously to this study were reanalyzed and one aquifer test was conducted during this study to determine hydraulic conductivity information for the ground-water-flow model. Particle-tracking analysis was used in conjunction with flow

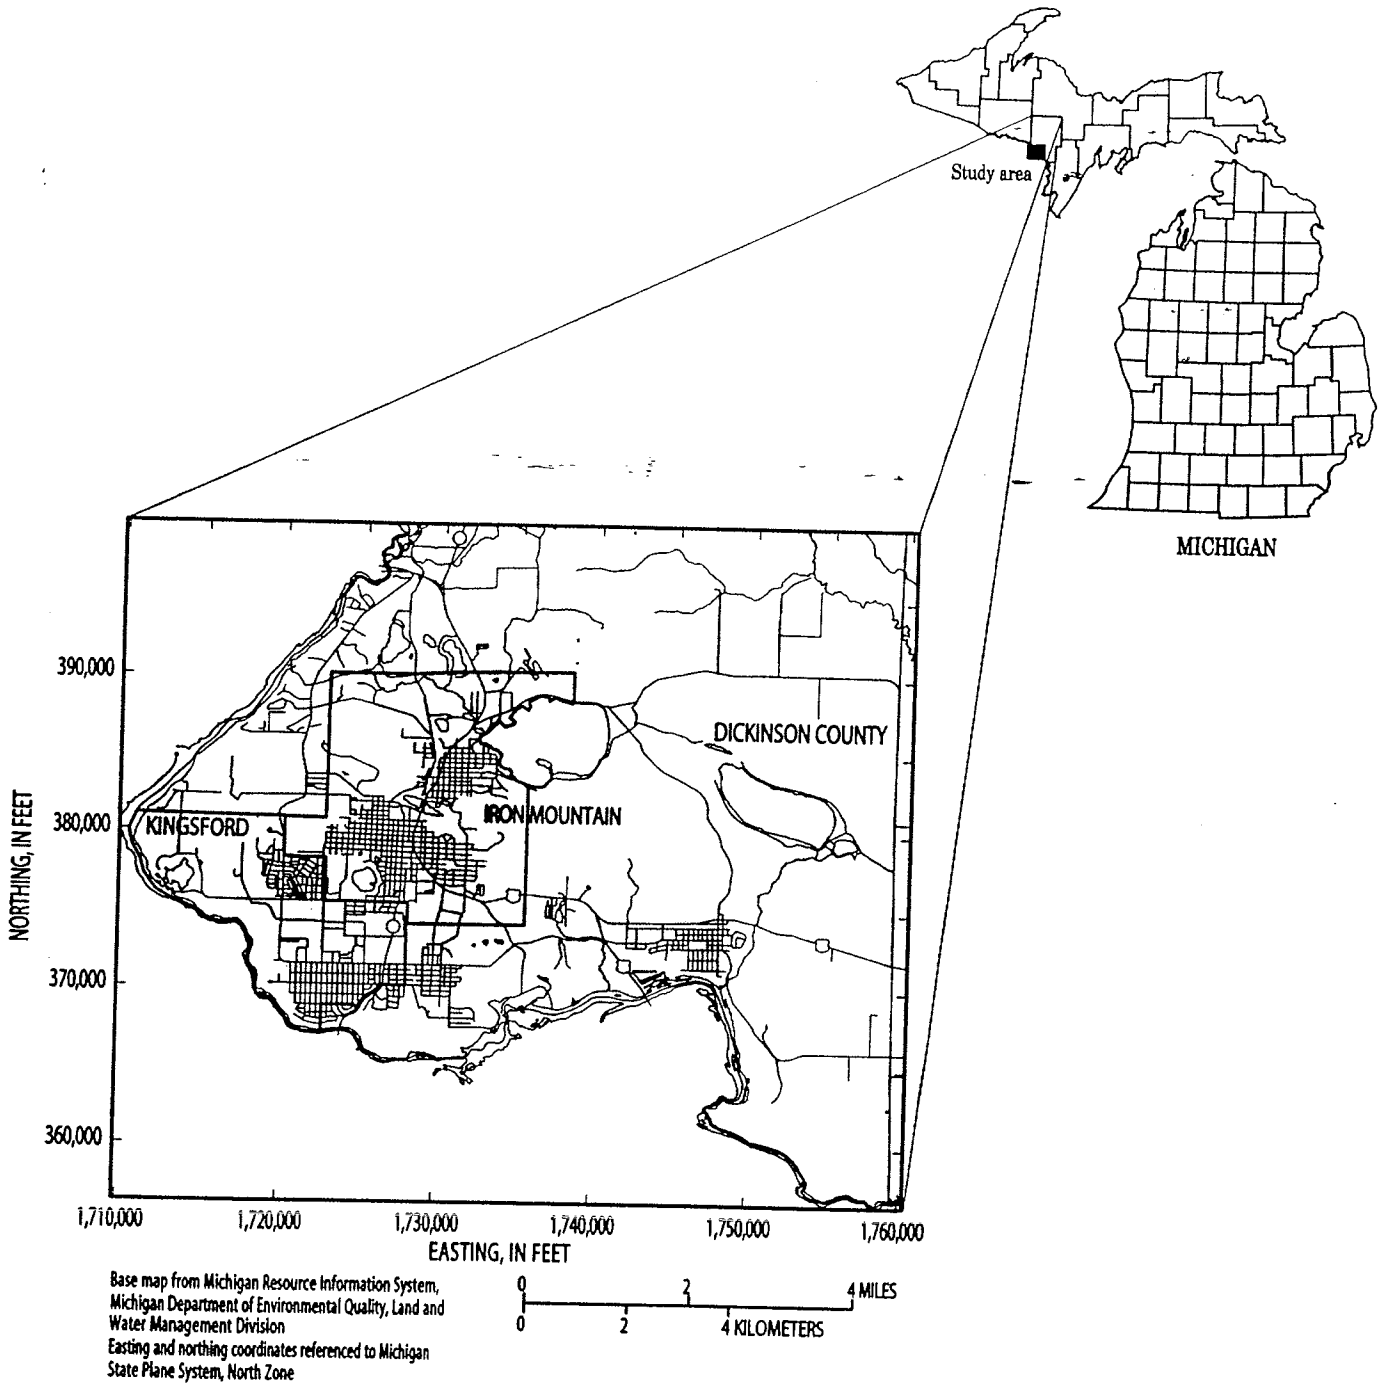

Figure 1. Location of Kingsford and Iron Mountain in the Upper Peninsula of Michigan.

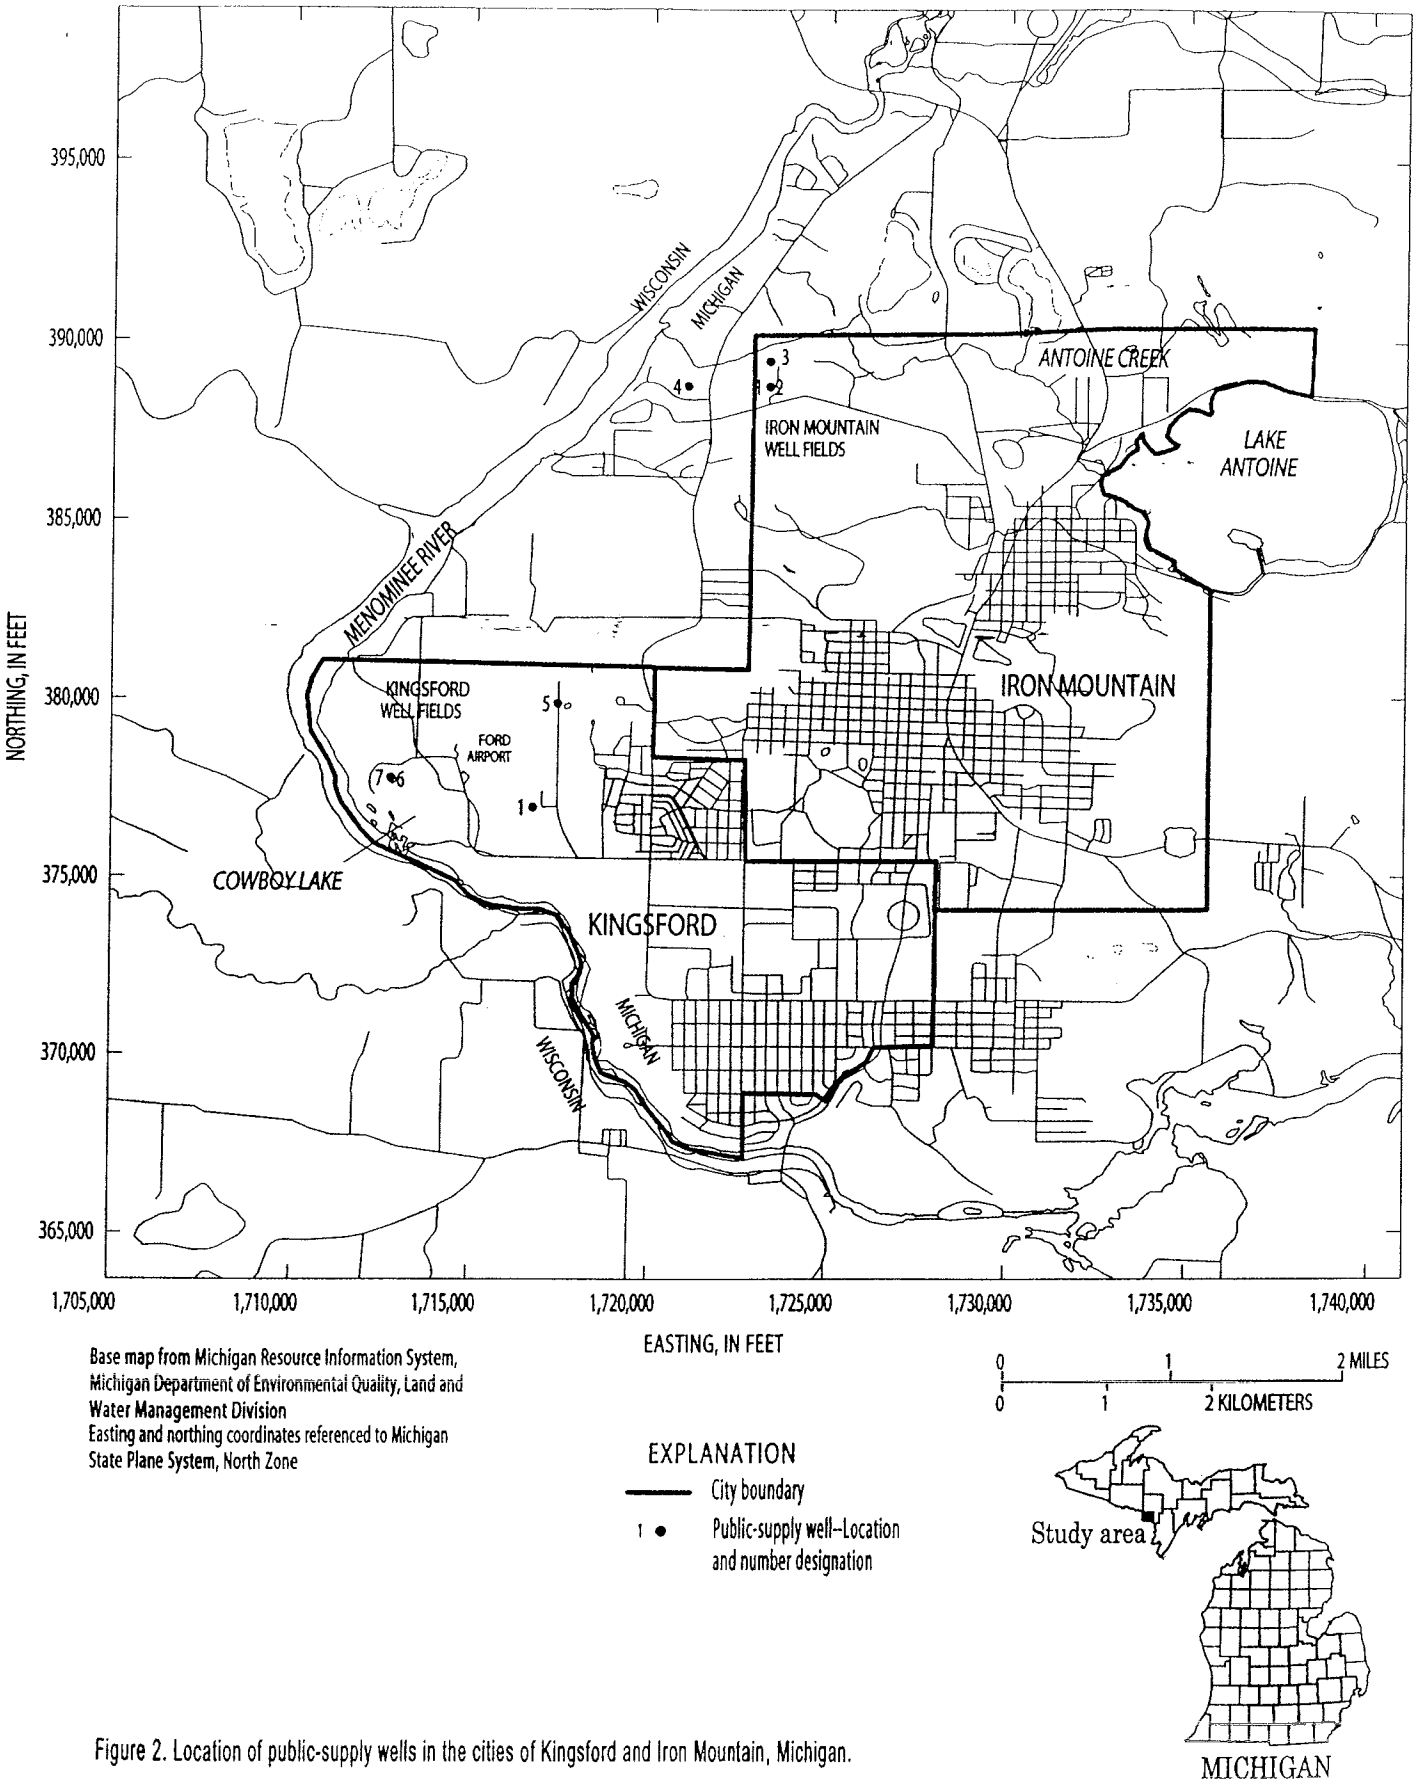

Figure 2. Location of public-supply wells in the cities of Kingsford and Iron Mountain, Michigan.

simulations to delineate the land surface and subsurface areas that contribute water to the public-supply wells. Model simulations are based on the U.S. Geological Survey Modular Three-Dimensional Finite-Difference Ground-Water Flow Model, MODFLOW-96 (McDonald and Harbaugh, 1988, 1996), which is a generalized code for ground-water-flow modeling. Areas contributing water to supply wells were determined using a particle-tracking post-processor package for MODFLOW (MODPATH, Pollock, 1989).

Previous Studies

Numerous studies have contributed to an understanding of the geology and hydrology of this area. Kingsford and Iron Mountain have evaluated potential areas for well-field development. These evaluations include test borings, aquifer tests, and geophysical surveys (Keck Consulting Services, Inc., 1974; Coleman Engineering Co., 1975, 1980, 1982, and 1987; Lynn M. Miller, P.E., 1976; Sundberg, Carlson, and Associates, Inc., 1989; and McNamee, Porter and Seeley, 1981 and 1990).

Two studies in the area (Engineering for Earth, Water, and Air Resources [EWA], 1986; 1987) focused on hydrogeologic conditions at a site in Kingsford that was used for manufacturing facilities. In this area, glacial kettles (depressions in the land surface formed by melting of ice blocks and subsidence of overlying deposits) were used as retention ponds for waste products. EWA's investigations included installation of monitoring wells and soil borings, and development of a ground-water-flow model to determine the potential effect of these waste-disposal pits on water quality, and the potential effect on Kingsford's water supply. Subsequent investigations have been conducted and indicate that although environmental contamination is present near historic industrial sites, it is unlikely that these areas pose any threat to the quality of water at either the Kingsford or Iron Mountain well fields.

Acknowledgments

The authors gratefully acknowledge the assistance of Darryl Wickman, Tony Edlebeck, George Groeneveld, and Al Muntz, city of Kingsford; and Jim Urbany and John Ellis, city of Iron Mountain, for providing information and access to the public-supply wells and providing other sources of information about the cities; Chuck Thomas, Drinking Water and Radiological Protection Division, Michigan Department of Environmental Quality, for providing copies of reports and information about geologic and hydrologic conditions in the areas; and Shirley Businski, Land and Water Management Division, Michigan Department of Environmental Quality, for providing information on public-supply wells. Sincere thanks also are given to homeowners and golf course owners, who permitted access to their wells for water-level measurements.

DESCRIPTION OF STUDY AREA

The cities of Kingsford and Iron Mountain are bounded by the Menominee River to the south and west, and by Trader Hill to the north (fig. 2). The Kingsford-Iron Mountain study area is within the Menominee River drainage basin which includes Dickinson County, Mich. and Florence County, Wisc. Historically, iron ore and timber industries were important to the area, while currently lumber and paper industries, tourism, and recreational activities support the area's economy. The geologic and hydrologic characteristics that affect ground-water flow in the study area are described below.

Geologic Setting

Most of the Kingsford-Iron Mountain area is underlain by Precambrian metasedimentary (Michigamme Slate) and metavolcanic (Badwater Greenstone and Quinnesec Formation) rocks. The Michigamme Slate consists of fine- to medium-grained metagraywacke and slate in massive or graded beds, whereas the Badwater Greenstone consists of massive, chloritized mafic volcanic rocks (Sims, 1990). The Quinnesec Formation consists of mafic and felsic volcanic rocks (Oakes and others, 1973). In the vicinity of Pine Mountain, Millie Hill, and Trader Hill (fig. 3), bedrock consists of metasedimentary rocks of the Vulcan Iron Formation, with alternating iron-rich and quartz-rich layers, and the Randville Dolomite,

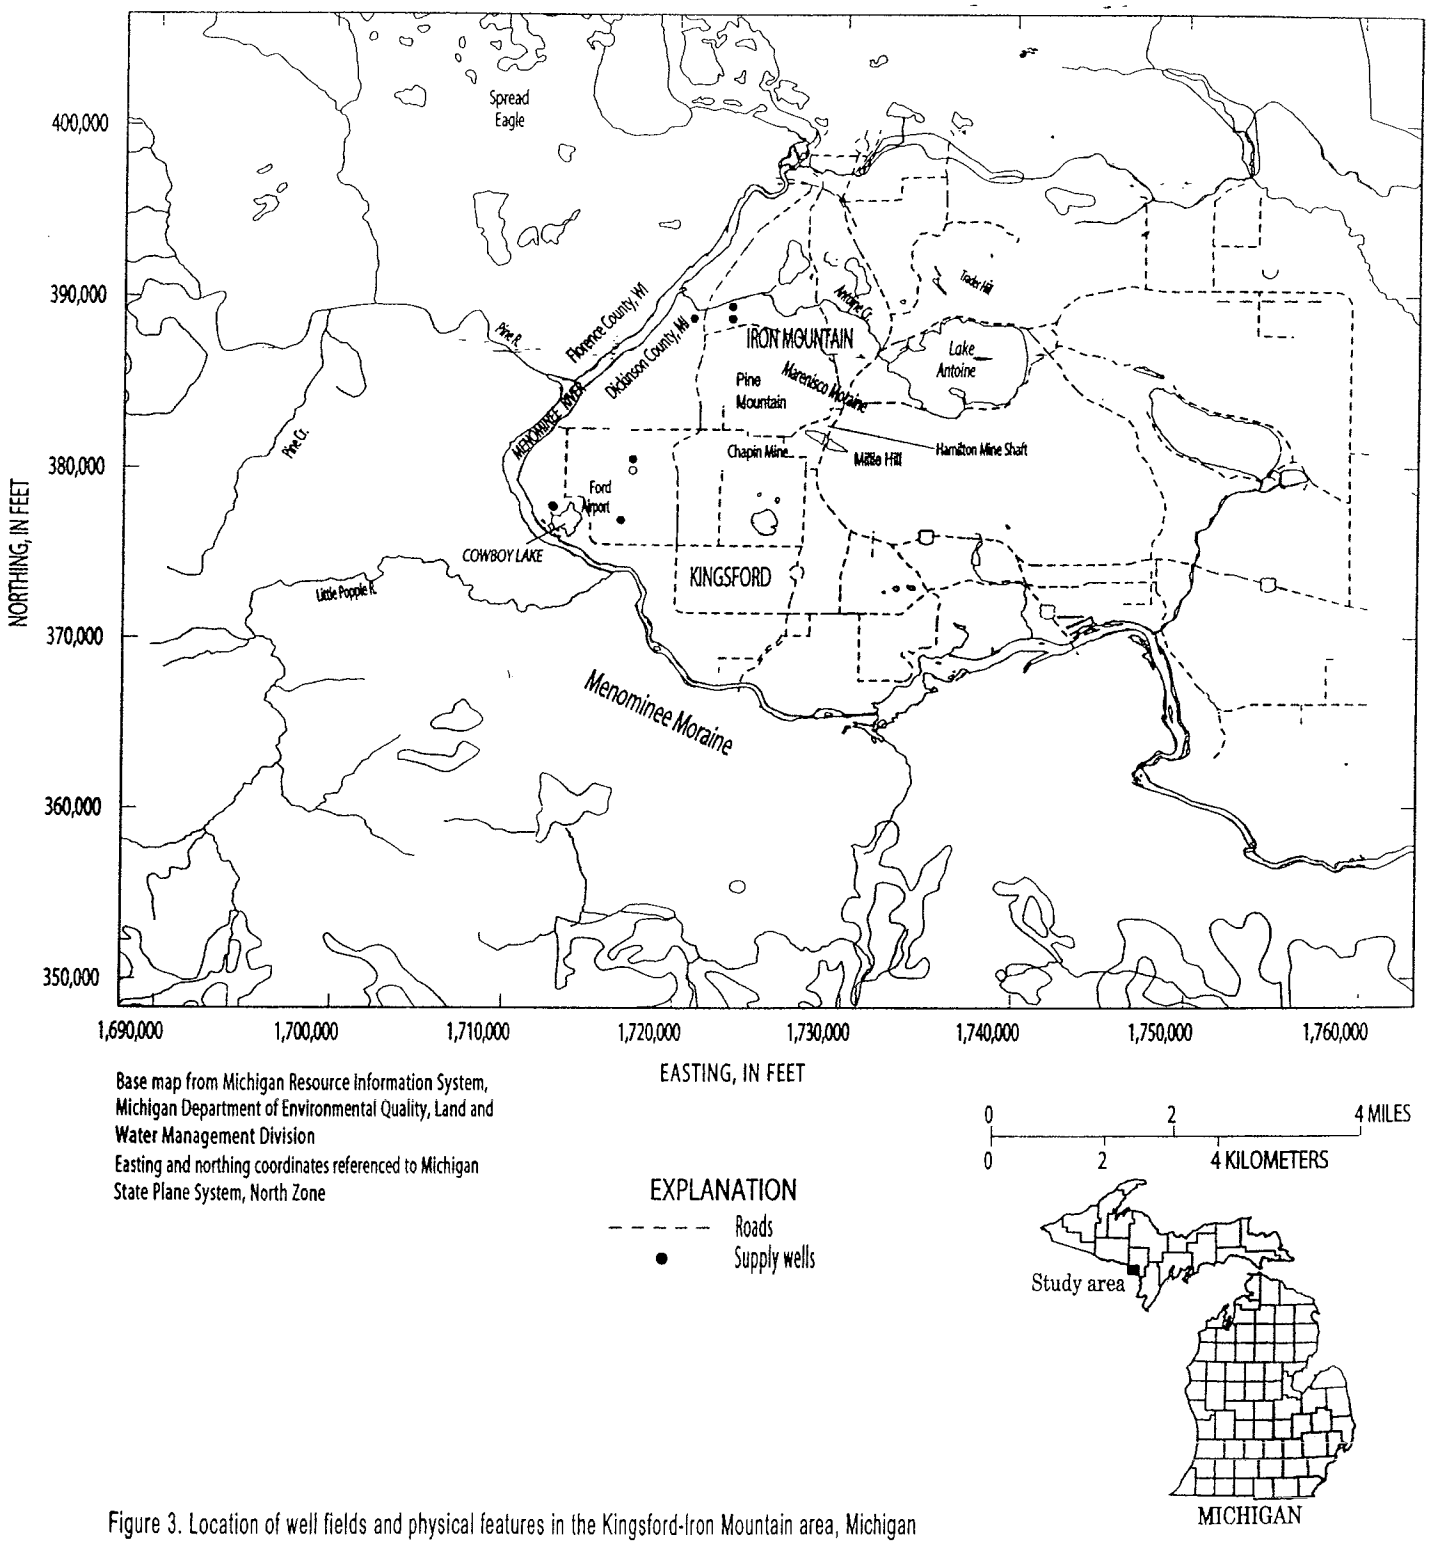

Figure 3. Location of well fields and physical features in the Kingsford-Iron Mountain area, Michigan

consisting of massive dolomite with detrital quartz grains and thick-bedded crystalline dolomite (Sims, 1990).

Bedrock is overlain by Pleistocene glacial deposits, except where bedrock is exposed along the Menominee River to the south and to the north near Spread Eagle, Wisconsin (Clayton, 1986). There also are isolated areas where bedrock is exposed (for example, Ford Airport), but these are of small areal extent. Glacial deposits range from 0 to about 380 ft in thickness. The Marenisco Moraine (Martin, 1955) forms a distinct ridge through the Kingsford-Iron Mountain area (fig. 3). Approximately parallel to this moraine and south of the Menominee River lies another moraine informally referred to as the Menominee Moraine.

Within the study area, glacial deposits generally consist of an upper terrace sand-and-gravel unit and a lower outwash sand-and-gravel unit separated by intermediate lacustrine silt and clay and eolian-silt layers (figs. 4, 5, and 6). These units are not regionally continuous and are absent in some isolated areas within Kingsford as indicated by boring logs. Towards the west and north, information obtained from well and geophysical logs indicates that upper terrace and lower outwash sand-and-gravel units are separated primarily by silt and fine sand.

The upper sand-and-gravel unit ranges from 0 to 160 ft in thickness and consists of medium to fine-grained sand with varying amounts of silt and gravel (Engineering for Earth, Water, and Air Resources, Inc., 1987). The confining unit ranges from 0 to 150 ft in thickness and consists of well sorted and well compacted fine silt and clay. In some areas, the silt and clay are absent, possibly due to partial burial and protrusion of stranded ice blocks that prevented silt deposition (Engineering for Earth, Water, and Air Resources, Inc., 1987). The lower sand-and-gravel unit ranges from 0 to 237 ft in thickness and consists of moderately well sorted fine to coarse sand with layers and lenses of silt and gravel (Engineering for Earth, Water, and Air Resources, Inc., 1987). The lower sand-and-gravel unit is underlain by a lodgement till or the Vulcan Iron Formation over much of the area. The lodgement till and Vulcan Iron Formation units range from 0 to 250 ft in thickness. West of the Menominee River, glacial deposits consist primarily of till or fluvial sediments that change conspicuously within relatively short distances (Clayton, 1986). The sediments consist of sand and gravel, which were deposited by glacial meltwater streams. The till consists of reddish brown or dark brown gravelly sandy loam with abundant surface boulders (Clayton, 1986, plate 1).

Hydrologic Setting

Precipitation averages about 29 in/yr over the Kingsford-Iron Mountain area. Mean monthly precipitation ranges from a minimum in February of 0.9 in to a maximum in August of 3.7 in. The study area receives about 62.8 in/yr of snowfall (Midwestern Climate Center, 1999). Precipitation averages about 30 in/yr in the Pine-Popple River Basin, west of the Menominee River, and is highest from late spring to early autumn (Oakes and others, 1973).

Two glacial aquifers (upper and lower aquifers) underlie the study area, based on previous studies and available well and boring logs. The upper aquifer in the glacial deposits consists of the upper terrace sand-and-gravel unit, whereas the lower aquifer in the glacial deposits consists of the lower outwash sand-and-gravel unit. The intermediate silt layer is a fairly effective barrier to hydraulic communication between the two aquifers. This lack of hydraulic communication is strongly indicated by substantial head differences between the two aquifers; water levels in shallow wells typically are 20-60 ft higher than water levels in deep wells (D.B. Westjohn, oral commun., 2000). Where the silt layer is absent in the Kingsford area, the upper and lower sand-and-gravel units compose one aquifer (Engineering for Earth, Water, and Air Resources, Inc., 1987). Hydraulic conductivities for the upper aquifer in the Kingsford area range from 9 to 0.9 ft/d based on tests performed by Engineering for Earth, Water, and Air Resources, Inc. (1987). Hydraulic conductivities average about 9 ft/d for the lower aquifer and range from 0.001 to 0.5 ft/d for the intermediate confining unit (Engineering for Earth, Water, and Air Resources, Inc., 1987).

An understanding of the hydraulic characteristics of glacial aquifers in the public-supply well field areas has been obtained from aquifer tests performed during investigations of

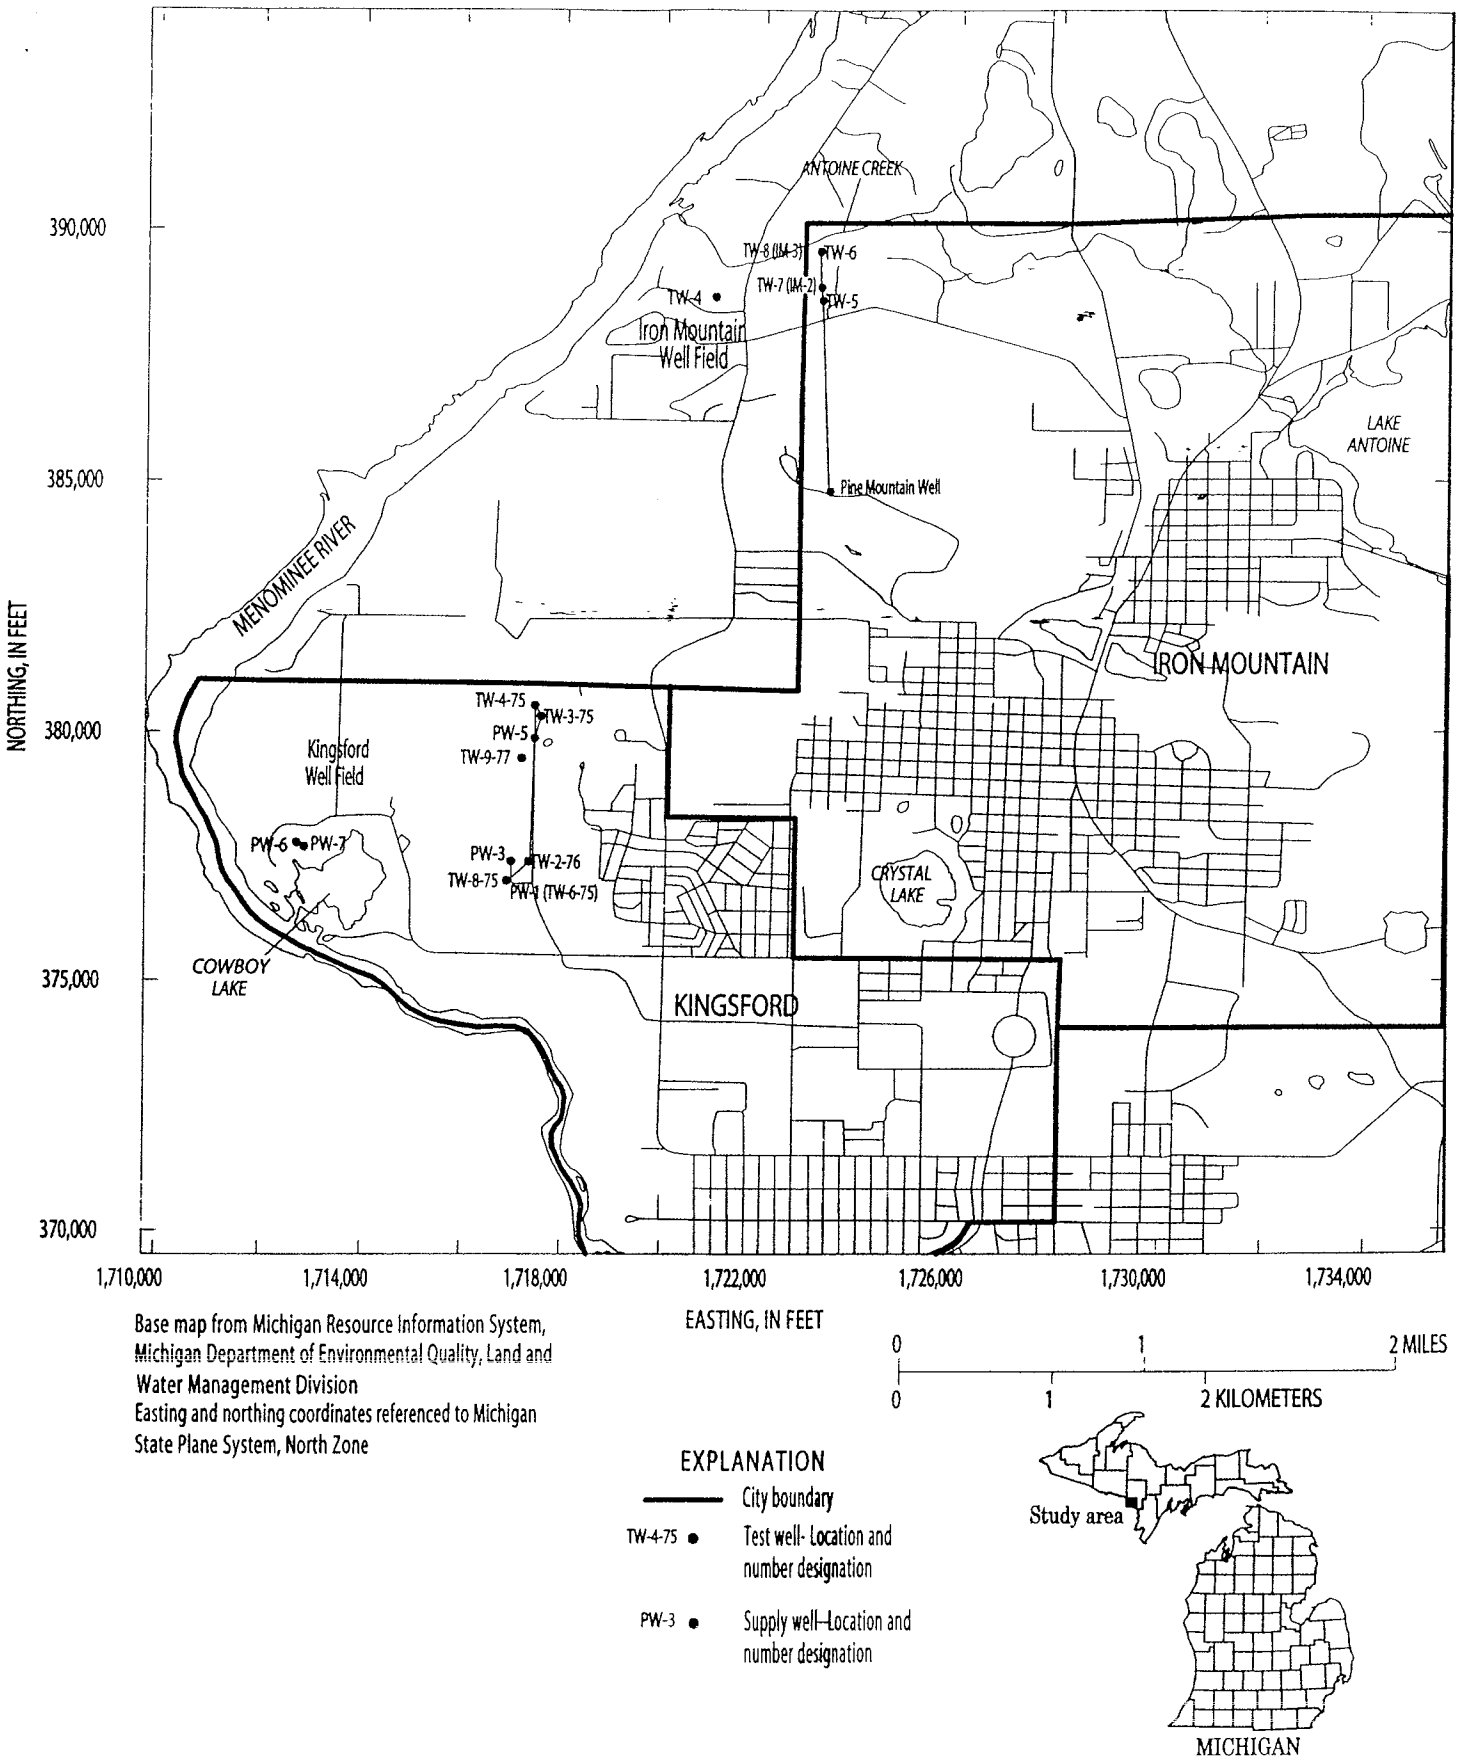

Figure 4. Location of lines of sections, test wells (TW), and supply wells (PW) in the Kingsford-Iron Mountain area, Michigan.

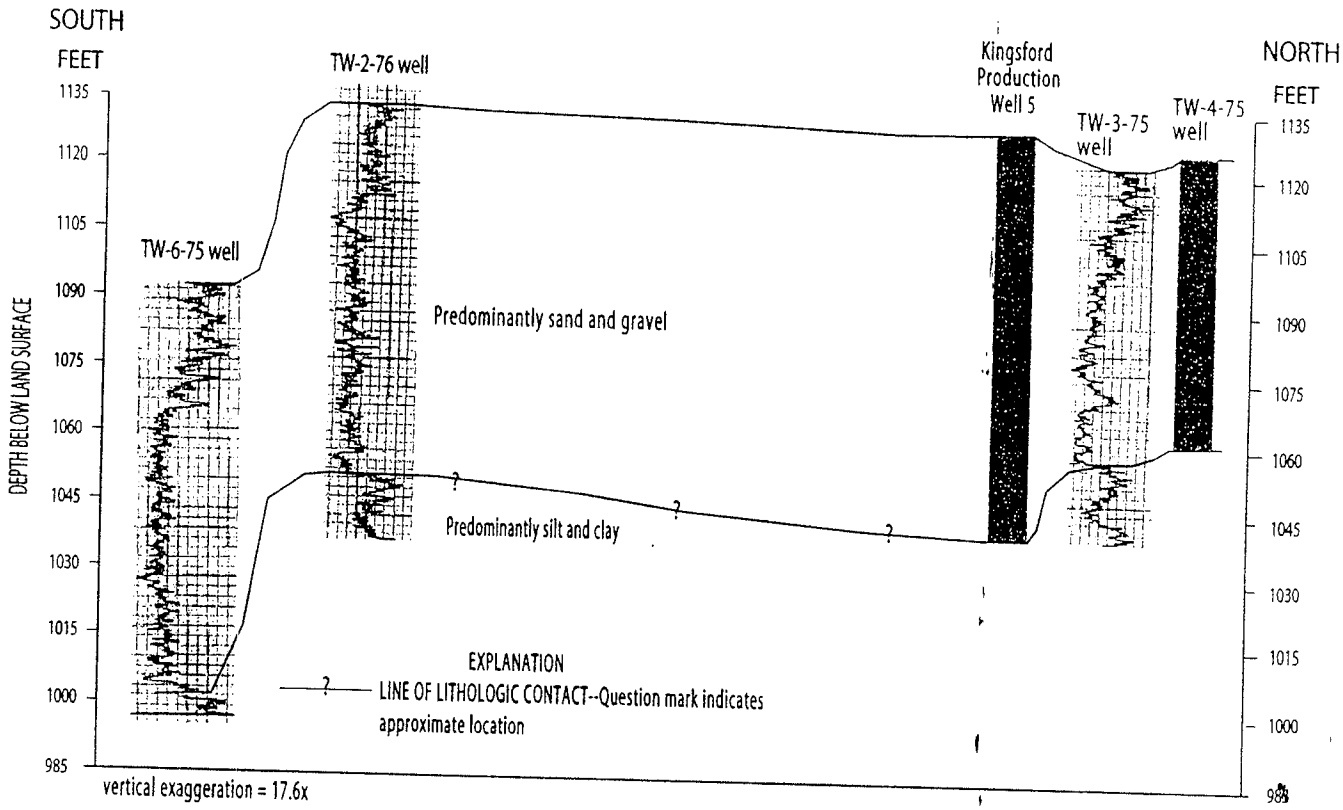

Figure 5. North-south section view of Kingsford's well field, Michigan. (Line of section shown in figure 4)

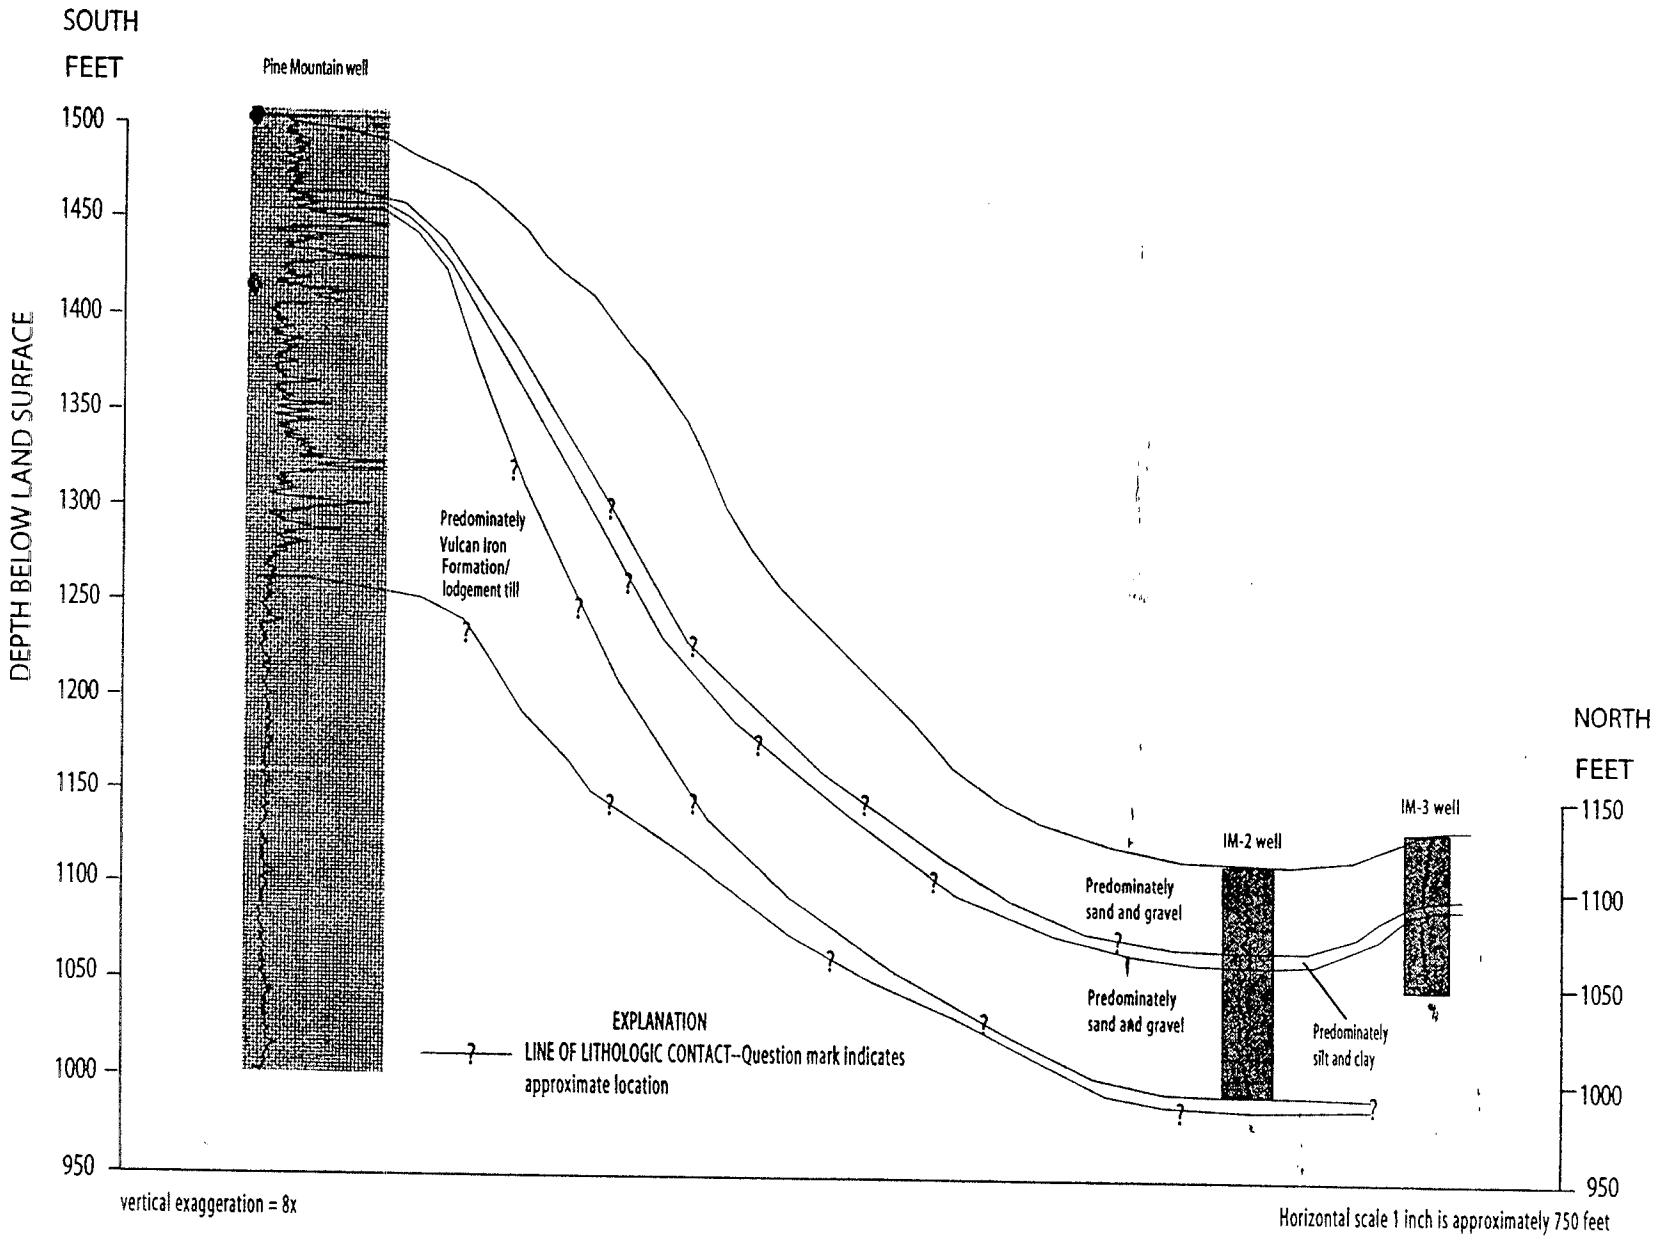

Figure 6. North-south section view of Iron Mountain's well field, Michigan. (Line of section shown in figure 4)

potential areas for well-field development (fig. 2, table 1). Aquifer tests of wells in the lower aquifer indicate ground-water leakage from overlying units. Iron Mountain's Well #4 is screened within the lower aquifer; however, in the immediate area surrounding well #4 the upper aquifer is missing.

Ground-water flow within the Kingsford-Iron Mountain area is primarily towards the surface-water bodies to the west and southwest and follows the topographic slope and the bedrock surface. Generally, the topographic slope follows the bedrock surface except within the central part of Kingsford where there is a bedrock low. Ground-water flow is probably confined primarily within the permeable sand-and-gravel units because Precambrian bedrock units appear to be largely unfractured and limit downward migration of ground water. However, bedrock consists of metasedimentary rocks in the vicinity of Pine Mountain and Millie Hill, and ground-water flow is locally controlled by these units where they are fractured.

CONCEPTUAL MODEL

The conceptual model describes ground-water flow within the Kingsford-Iron Mountain and surrounding areas and includes a definition of the position and thickness of aquifer and confining units, boundaries, and the flow system. Geologic units within the Kingsford-Iron Mountain area can be divided into layers that control ground-water flow. Four units were used to conceptualize the ground-water-flow system although not all units are present throughout the study area. These units consist of an upper permeable sand-and-gravel unit, an underlying confining unit consisting of silt and clay, a lower permeable sand-and-gravel unit, and a lowermost unit consisting of sandstone, dolomite, or lodgement till (where they are present). The bedrock of the Vulcan Iron Formation and the Randville Dolomite and the lodgement till of the glacial unit are poorly permeable and were combined in the lowermost unit because of their similar hydraulic properties.

Table 1. Estimated transmissivities for the glacial aquifers underlying Kingsford and Iron Mountain well fields, Michigan

Well field	Well numbers	Aquifer	Transmissivity (feet squared per day)
Kingsford	1, 5	upper aquifer	9,100 – 11,400
	6, 7	lower aquifer	2,800 – 12,700
Iron Mountain	1,2,3	lower aquifer	4,000 – 8,700
	4	lower aquifer	24,100

Although these units are poorly permeable, some domestic wells withdraw water from the bedrock; however, a few hundred feet of borehole must be open to a wellbore to provide an adequate supply. Geologic information obtained from logs of public-supply and domestic wells and geophysical logs were used to delineate the extent of the ground-water-flow system units.

Ground-water-flow systems have physical boundaries, which are formed by the presence of an impermeable body of rock or a large body of water, or hydrologic boundaries, which include ground-water divides and streamlines. Regional physical boundaries to the flow system are formed by the boundaries of the Menominee River drainage basin that extends west into Wisconsin and east into Michigan. Boundaries for the local-flow system in the Kingsford-Iron Mountain area consist primarily of bedrock and surface-water bodies in Michigan and Wisconsin that affect flow to the Menominee River. Locally, ground-water flow is affected by physical boundaries formed by bedrock highs south of the Menominee River and north of Iron Mountain's well fields, and by surface water bodies including Lake Antoine on the east, and the Pine and Little Popple Rivers on the west. Ground-water-flow divides are assumed to coincide with the surface-water divides which follow topographic highs and the impermeable bedrock in this area. Local hydrologic boundaries consist of streamlines, which are perpendicular to the ground-water-flow direction along the east and northeast. The lower boundary is formed by the upper surface of the Michigamme Slate, Badwater Greenstone, and Quinnesec Formations and is considered to be poorly permeable.

A preliminary understanding of ground-water-flow directions can be made on the basis of surface-water elevations taken from topographic maps of the area, ground-water levels measured during this study, and previous reports covering part of the study area. For this study, water levels were measured in 28 domestic, irrigation, and observation wells. Water levels recorded on well logs and average drawdown measurements obtained for each of the public-supply wells also were analyzed to understand ground-water-flow directions. Regional ground-water flow is towards the Menominee River and follows the direction of the regional topographic slope and the bedrock surface (fig. 7).

SIMULATION OF GROUND-WATER FLOW

Simulation of ground-water flow is made possible by first developing a conceptual model of the flow system and then developing a numerical model that is consistent with the conceptual model. The model area consists of the Kingsford-Iron Mountain area and surrounding parts of Dickinson County, Michigan and Florence County, Wisconsin. This larger area (larger than the cities of Kingsford and Iron Mountain) was modeled so as to eliminate boundary effects on the ground-water-flow solution in the interior portion of the model area by allowing natural physical and hydrologic boundaries to be chosen, as well as to investigate whether ground water moved beneath the Menominee River as possibly indicated by the high change in ground-water levels from Pine Creek to the Menominee River.

Numerical Model

The U.S. Geological Survey Modular Three-Dimensional Finite-Difference Ground-Water Flow Model (MODFLOW-96, McDonald and Harbaugh, 1996) was the computer code used to simulate ground-water flow in the Kingsford-Iron Mountain area.

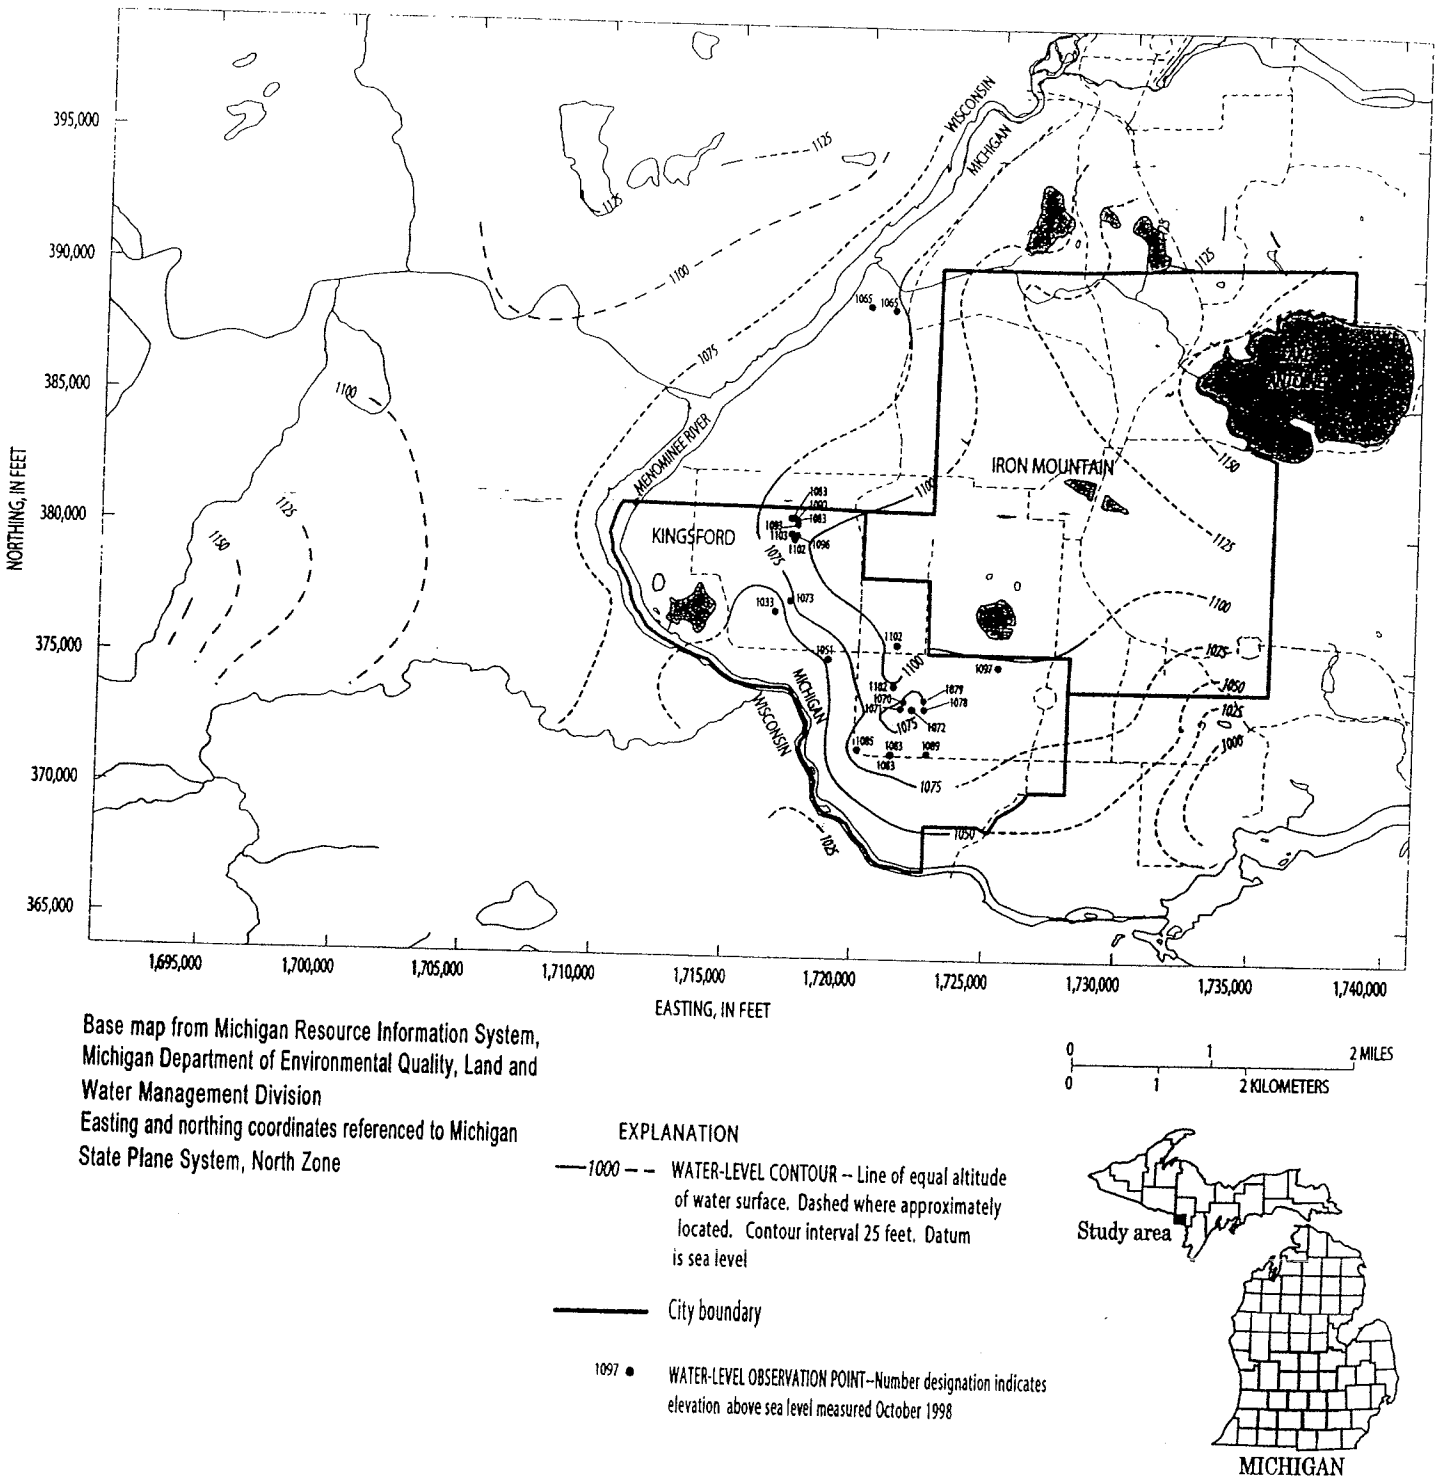

Figure 7. Ground water levels in the upper aquifer in the Kingsford - Iron Mountain area, Michigan.

This code allows the simulation of steady-state ground-water flow in two dimensions with leakage between model layers; no ground-water storage or temporal discretization terms are required. All water entering the model area through the boundaries or as recharge is assumed to leave the model area through the boundaries, rivers, or wells. The Kingsford and Iron Mountain wells have been in operation for 8 to 25 years; therefore the ground-water flow system is considered to be in steady state and water is not lost or gained from storage.

Various assumptions were made in the numerical simulation of ground-water flow. Recharge to ground water was assumed to differ over the model area depending on the presence or absence of glacial till. Recharge is assumed to be zero in areas where till or bedrock is at or very near the surface. In other areas recharge initially was assumed to be 10 in/yr. The assumption of no recharge to areas of till and bedrock highs was investigated during model calibration. Evapotranspiration of ground water also was assumed to be zero because recharge was applied to the upper surface of the model (water table), where the effects of evapotranspiration are expected to be small, and because of the regional scale of the model. Ground water was assumed to flow primarily through the glacial sand-and-gravel units. Glacial deposits are known to vary considerably with varying lithologies and thicknesses over short distances. This variability makes exact representation of the detailed hydrogeology impossible in the numerical model. Thus, hydraulic properties of the glacial deposits are generalized to represent the regional ground-water-flow system. The underlying lodgement till and bedrock units of the Vulcan Iron Formation and Randville Dolomite were simulated as a low permeability layer. The lowermost Precambrian bedrock units were simulated as impermeable boundaries. North of the Chapin Mine, ground water is withdrawn from the Hamilton Mine Shaft that extends deep into the underlying bedrock units and is discharged into Lake Antoine (fig. 3). A probable hydraulic connection is present between the bedrock and Lake Antoine based on that water levels in the mine shaft only can be lowered approximately 2 feet even with extensive pumping and the high gradient from the lake to the shaft. It is possible that the withdrawal of ground water from this mine shaft affects local ground-water levels in the immediate vicinity; however, this area is over 1.5 mi from the public-supply well fields and is not thought to affect hydrologic conditions there. Therefore, these conditions were not simulated in the model.

Model Grid and Layers

The modeled area is rectangular and consists of about 64 mi^2 (fig. 8). The area is 6.7 mi long (north-south) and 9.5 mi wide (east-west). This area is horizontally discretized into a variably spaced grid of cells in 213 columns and 204 rows. In the central portion of the model, each cell is 100 by 100 ft. Cell spacing increases initially by a factor of 1.25 for 5 rows/columns and then by a factor of 1.5 out to a maximum grid spacing of 1,029 ft. This maximum spacing was selected so as not to exceed a maximum row to column spacing ratio of 10:1. Each grid cell represents the average aquifer properties in the volume of aquifer represented by the cell; any variations in properties that are within a grid cell only can be represented in the model averages.

The model area is vertically discretized into three model layers. Layer 1 represents the upper aquifer in the glacial deposits. This aquifer is under unconfined conditions with water levels representing the water table. Layer 2 represents the lower aquifer in the glacial deposits. The lower aquifer represented in layer 2 is simulated as convertible and can be either confined or

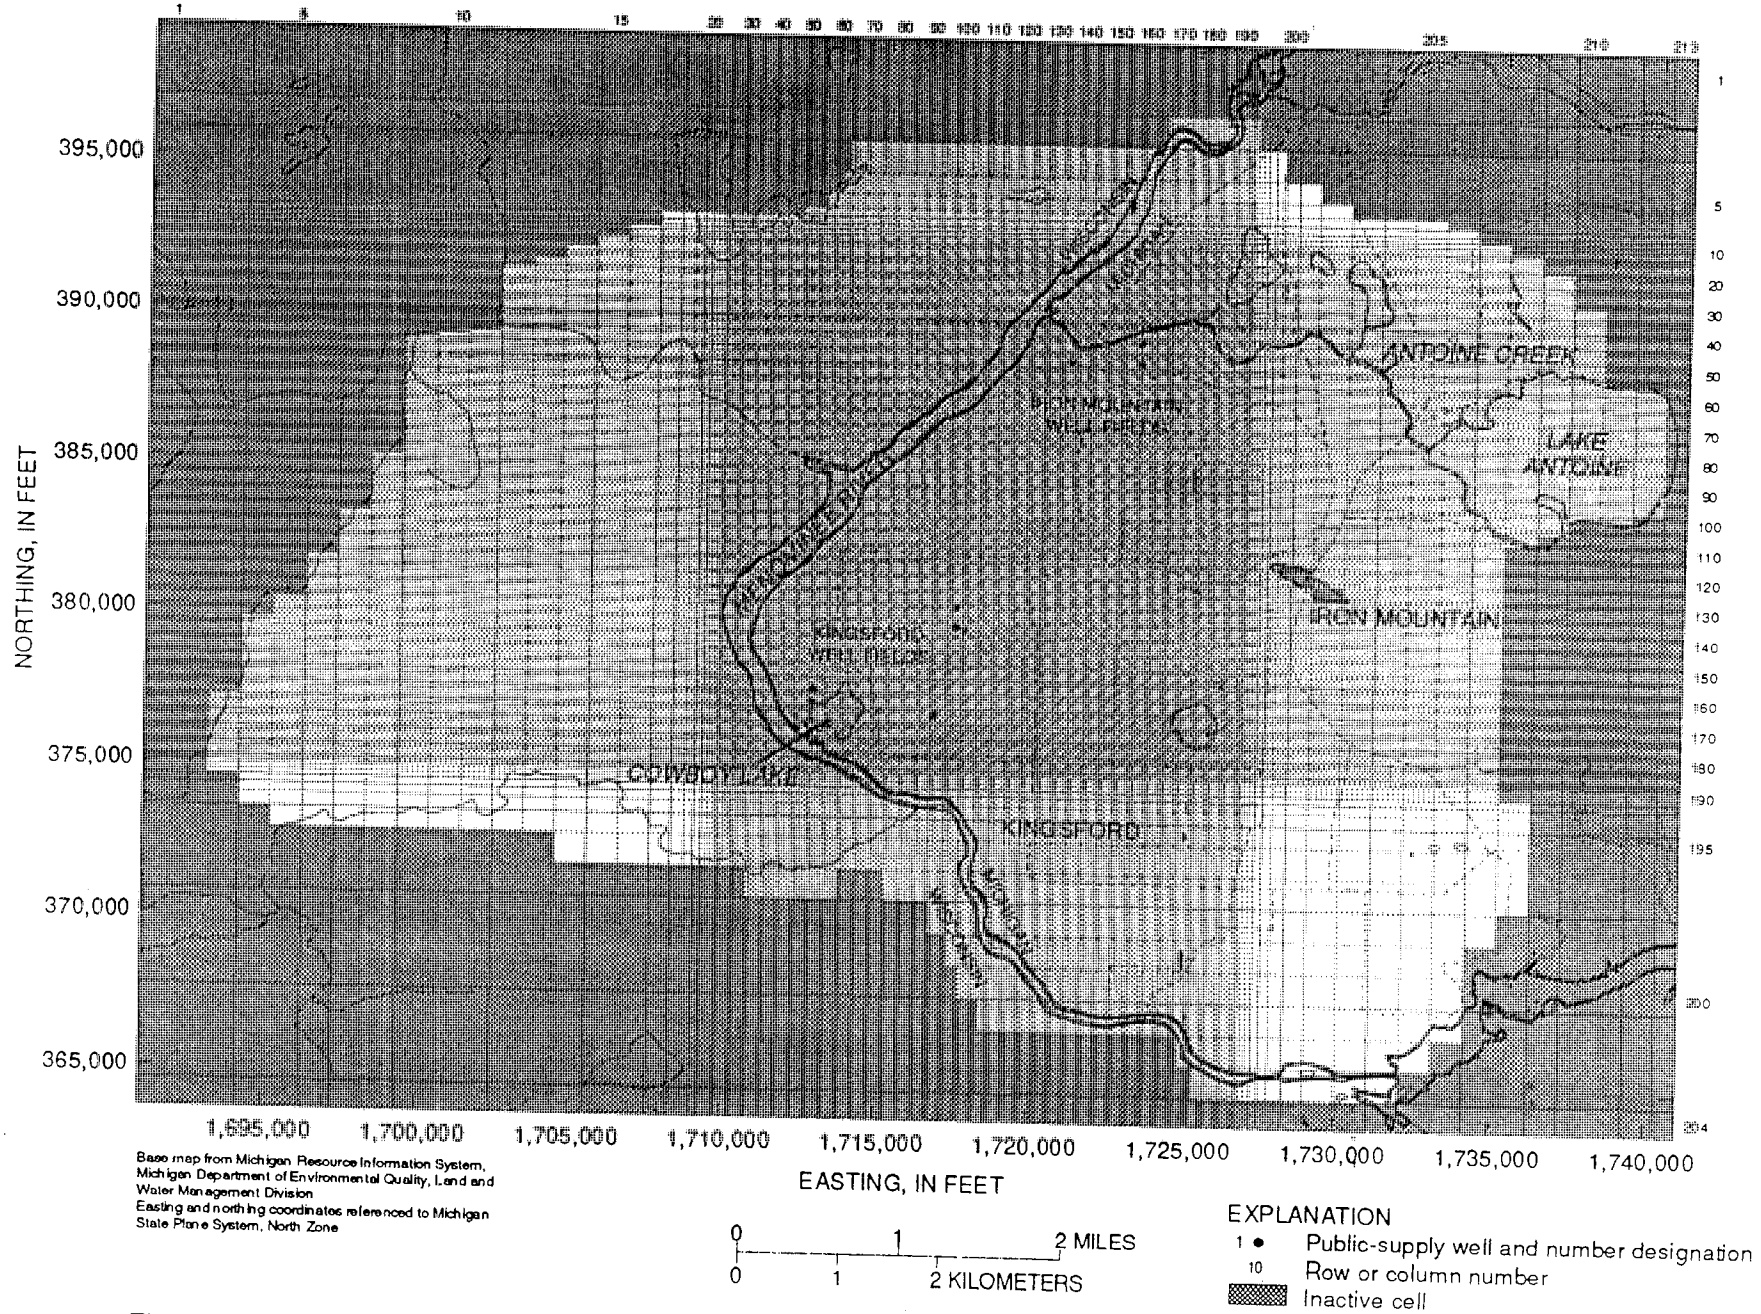

Figure 8. Model grid for simulating the ground-water-flow system underlying the Kingsford-Iron Mountain area, Michigan.

unconfined depending on the position of the water table. The intermediate confining unit that separates the upper and lower aquifers was included only in the leakance term between layers 1 and 2. The bottom model layer (layer 3) represents either metasedimentary rocks (in the vicinity of Pine Mountain, Millie Hill, and Trader Hill) or lodgement till (over the remaining area) and also is represented as convertible.

Model layer	Hydrologic unit
1	Upper aquifer in glacial deposits
2	Lower aquifer in glacial deposits
3	Lodgement till/ metasedimentary rocks

Land-surface information for most of the model area is available from a digital 1:100,000 topographic quadrangle map for Iron Mountain. This information was interpolated to a grid with a 50 ft spacing. Additional point-altitude data were taken from the topographic quadrangle map for Iron Mountain SW. This information was contoured over the model area to create land-surface elevations, which constitute the top of glacial deposits (fig. 9). The land surface is characterized by steep gradients in the vicinities of Pine Mountain, Millie Hill, and Trader Hill.

Layer surfaces were determined based on logs of domestic and public-supply wells obtained from Geological Survey Division, Michigan Department of Environmental Quality; Statewide Ground-Water Database, MIRIS-Geologic Resource Mapping Unit, Michigan Department of Environmental Quality; and Wisconsin Geologic and Natural History Survey (figs. 10-12). The top of the silt unit formed the bottom of layer 1 and the silt unit thickness was assigned to layer 2. In areas where the geologic materials composing a layer are absent, the layer is assigned a minimal thickness and the hydraulic properties of the overlying layer. Information for the Wisconsin part of the model area did not differentiate the glacial deposits into separate vertical units; therefore, on the western side of the Menominee River, glacial deposits are modeled as the upper layer with layer 2 assigned a 1 ft thickness and the hydraulic conductivity of the overlying layer. Additional delineation of layer surfaces in areas of sparse data was done by extrapolating from known nearby points, primarily within Wisconsin where few well logs are available. In the vicinity of Pine Mountain, Millie Hill, and Trader Hill, till overlies the bedrock units and the sand-and-gravel units are missing. Outcrops provide additional control for the delineation of the bedrock surface, especially in Wisconsin where outcrops indicate that glacial deposits are thin.

Boundary Conditions

Model boundaries extend approximately 1 mi north of the Iron Mountain well field, approximately 1 mi south of the Kingsford well field, and approximately 2 mi east and 3 mi west of the well fields (fig. 8). These boundaries are based on surface-water elevations and topographic information, and are represented by specified head, specified flux, and head-dependent flux conditions. Specified head boundaries (also referred to as constant head boundaries) are modeled by specifying head values that do not change during numeric simulation. Specified flux boundaries can be modeled by specifying the flux equal to zero to represent ground-water-flow divide boundaries and streamlines. Head-dependent flux boundaries are modeled by specifying a conductance, which limits the amount of water that can enter or leave any cell.

Specified head boundaries are used to represent hydraulic conditions along parts of the east and west model boundaries and are

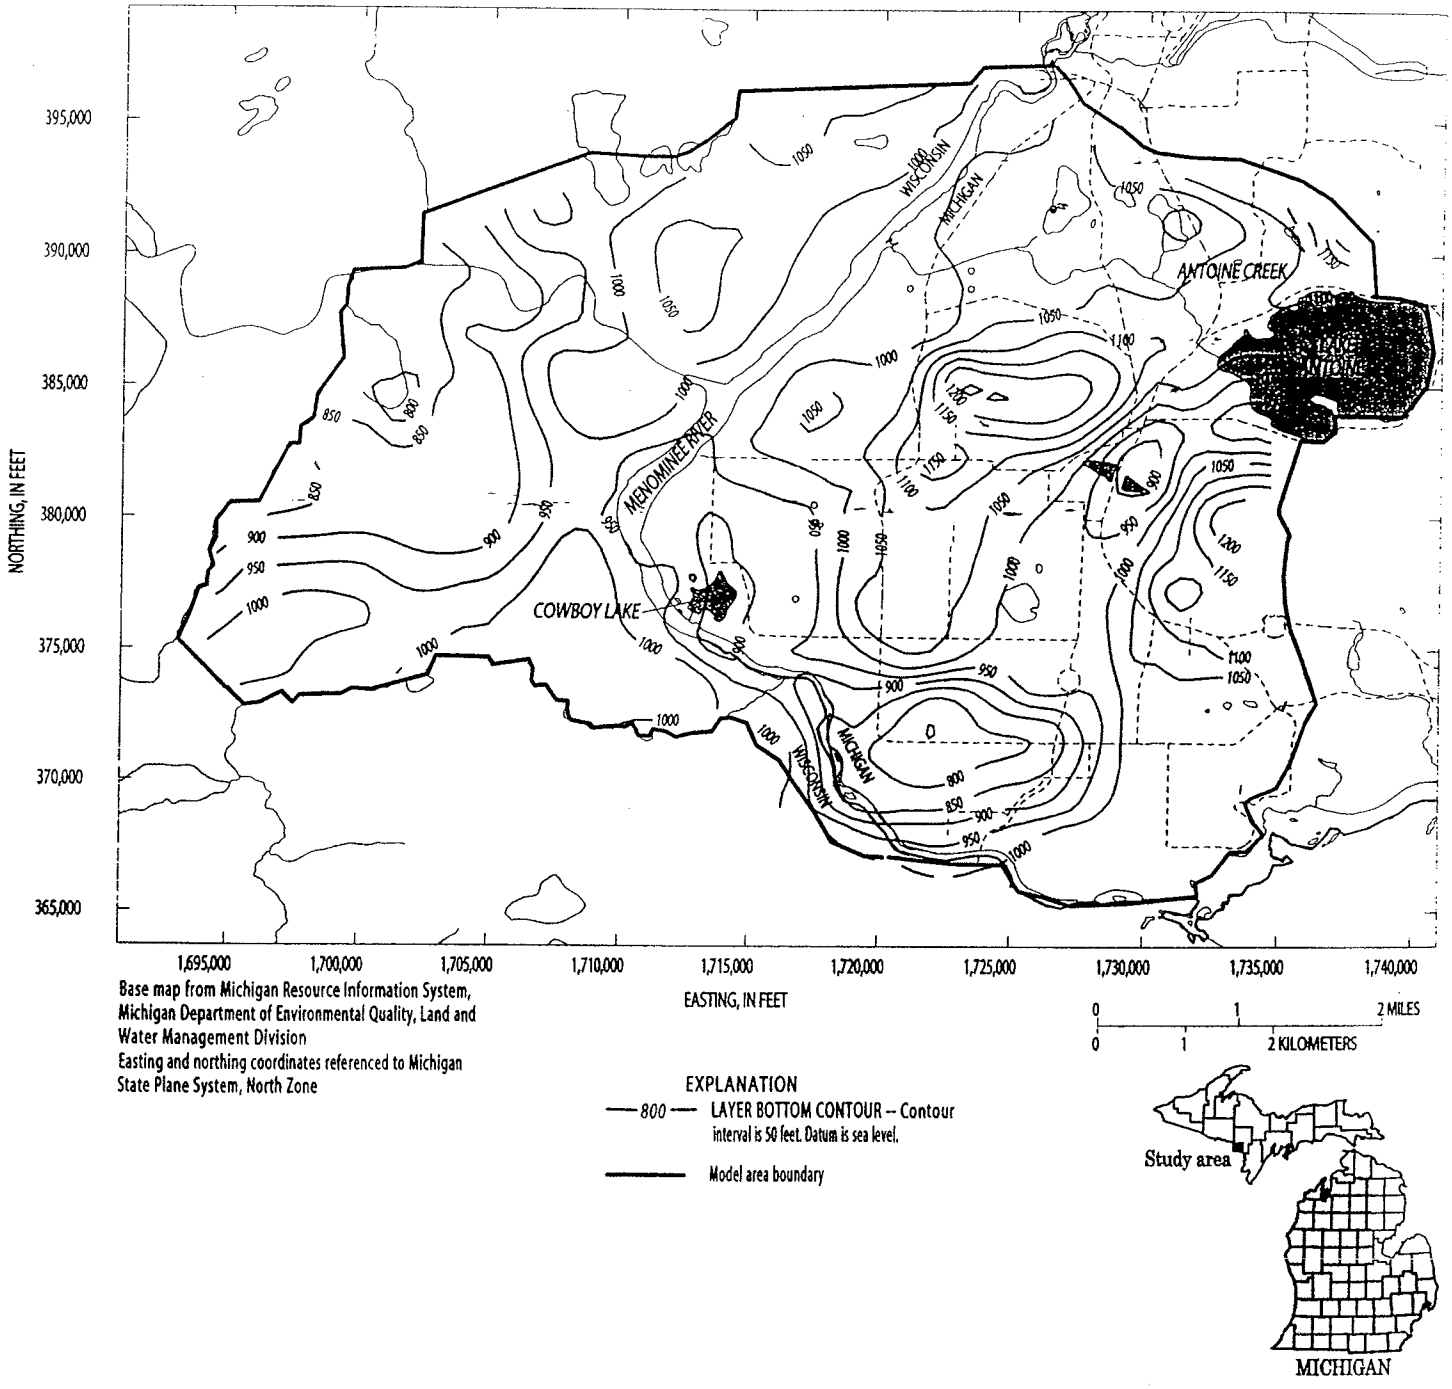

Figure 12. Estimated configuration of the bottom of the lodgement till and metasedimentary rocks (model layer 3), Kingsford-Iron Mountain area, Michigan.

based on surface-water elevations (fig. 13). Specified head boundaries also were used to represent the southernmost part of the Menominee River. Specified flux boundaries with flux equal to zero are used to represent natural physical boundaries formed by outcropping or shallow bedrock along parts of the north and south model boundaries. Specified flux boundaries with flux equal to zero also are used to represent ground-water-flow divides and streamlines along parts of the north and west boundaries. Finally, head-dependent flux boundaries are used to represent Lake Antoine along part of the east boundary and three small lakes along the west boundary.

In areas where a natural physical boundary does not exist, specified head boundaries located far from the well fields were used, based on available water-level data. After model development, sensitivity of model results to boundary conditions were analyzed. Fluxes through cells forming specified head boundaries were compared for simulations in which public-supply wells were being pumped and when wells were idle. As an additional check on the ground-water-flow solution, specified head boundaries were changed to specified flow boundaries and the solutions compared. The effect of stresses induced by pumping (on the assumption of no-flow across streamlines) also was investigated.

All boundaries of layer 2 are the same as those of layer 1, except that no-flow boundaries are located in the area of Lake Antoine, because the lake does not penetrate the lower sand-and-gravel unit. Layer 3 is bounded by no-flow boundaries. In layers 1 and 2, the Chapin Mine area of the model is represented by inactive (no-flow) cells and by head-dependent flux cells in layer 3. In this area, glacial deposits are relatively thin and unsaturated, and ground water is present only in the bedrock unit below the glacial deposits.

Hydraulic Properties

Hydraulic properties used in model simulations include layer hydraulic conductivities and leakances, recharge rates, and streambed conductance. Aquifer hydraulic properties and leakances affect ground-water flow through and between model layers. Recharge rates indicate the amount of water movement through the upper surface of the model. Streambed conductance affects vertical flow of ground water from an aquifer to a stream or from a stream to an aquifer.

Based on interpretation of well and geophysical logs, eleven zones were used to describe conditions within the three layers (table 2, figs. 14-16). The upper and lower aquifers were separated into different zones based on calculated horizontal hydraulic conductivities from aquifer-test analyses. Transition zones were added to reduce the difference in hydraulic conductivities between zones in some areas. Initial estimates of hydraulic conductivity for the zones within each layer were based on calculated hydraulic conductivities from aquifer-test analyses and on representative values estimated by Freeze and Cherry (1979) for the geologic materials present in the area.

Leakances as described by McDonald and Harbaugh (1988) are based on the layer thicknesses and the vertical hydraulic conductivity for each layer. The initial estimate of leakance between layers 1 and 2 was based on the thickness and assigned values for the hydraulic conductivity of the confining unit that separates the upper and lower aquifers. Vertical hydraulic conductivities were assigned based on the type of geologic materials present and consisted of zones representing till in the vicinity of Pine Mountain and Millie Hill, silt and clay in the south Kingsford area and to the north near Iron Mountain Well #4, and silt and silty sand over the rest of the area

Table 2. Initial horizontal and vertical hydraulic conductivity estimaes for layer zones in the ground-water-flow model

Layer	Zone	Horizontal hydraulic conductivity (feet per day)	Vertical hydraulic conductivity (feet per day)
1	1	100	1.0
	2	5	.05
	3	25	.25
	4	50	.5
2	5	120	1.2
	6	5	.05
	7	25	.25
	8	250	2.5
3	9	.02	.002
	10	.002	.0002
	11	.0002	.00002

(fig. 17). These vertical hydraulic conductivities then were divided at each grid cell location by the layer thickness. The resulting values for leakance between layers 1 and 2 ranged from 3.8×10^{-6} to 2.5×10^{-3} /d (fig. 18). The initial estimate of leakance between layers 2 and 3 was based on the vertical hydraulic conductivity of the geologic materials present and the thickness of the over- and underlying layers. The resulting values for leakance between layers 2 and 3 ranged from 1.8×10^{-7} to 4×10^{-3} /d (fig. 19). Initial estimates of vertical hydraulic conductivity were assumed to be 0.01 times the horizontal hydraulic conductivity for each zone.

Recharge was assumed to differ in areas depending on the type and thickness of glacial deposits and was applied to the top model layer. In areas of surficial till, and in areas where the bedrock is located near the land surface, recharge was assumed to be zero. Over the rest of the area, recharge initially was assigned a value of 10 in/yr. Estimates of average discharge obtained from three nearby U.S. Geological Survey (USGS) gaging stations equaled 18.3 in/yr from 1914 to 1996 for the Menominee River near Florence, Wisc. (USGS gaging station 04063000); 15.1 in/yr from 1914 to 1997 for the Menominee River at Twin Falls near Iron Mountain, Mich. (USGS gaging station 04063500); and 13.8 in/yr from 1993 to 1997 for the Menominee River at Niagara, Wisc. (USGS gaging station 04065106, Water Resources Data for Michigan, Water Years 1996 and 1997). These discharges represent an upper limit for recharge because they include both baseflow and runoff. Actual estimates of baseflow could not be determined because of the presence of numerous control structures along the Menominee River.

In MODFLOW (McDonald and Harbaugh, 1988), streambed conductance is calculated as the product of the hydraulic conductivity of the streambed materials, stream length, and stream width, divided by the streambed thickness. Stream lengths for cells representing the Menominee River were equal to the length of the cell (fig. 8). Stream widths were assumed to be equal to approximately 100 ft. Stream lengths for cells representing the Pine River, Pine Creek, and Little Popple River in Wisconsin were equal to the length of the cell. Stream widths were assumed to equal 10 ft except along one section of the Pine River where the width was assumed to equal 100 ft. Stream lengths and widths for cells representing Antoine Creek were assumed to be 10 ft. Streambed thicknesses were assumed to be 1 ft. Hydraulic conductivities of the streambed materials were initially assigned a value of 10 ft/d, except for the section of Antoine Creek in the area immediately north of Iron Mountain Well #3 which was assigned an initial value of 1 ft/d. In this area, Coleman Engineering Company (1980) observed that the creek bottom consisted of silty sand which limits the direct flow of water from the creek to the well at this location. Horizontal

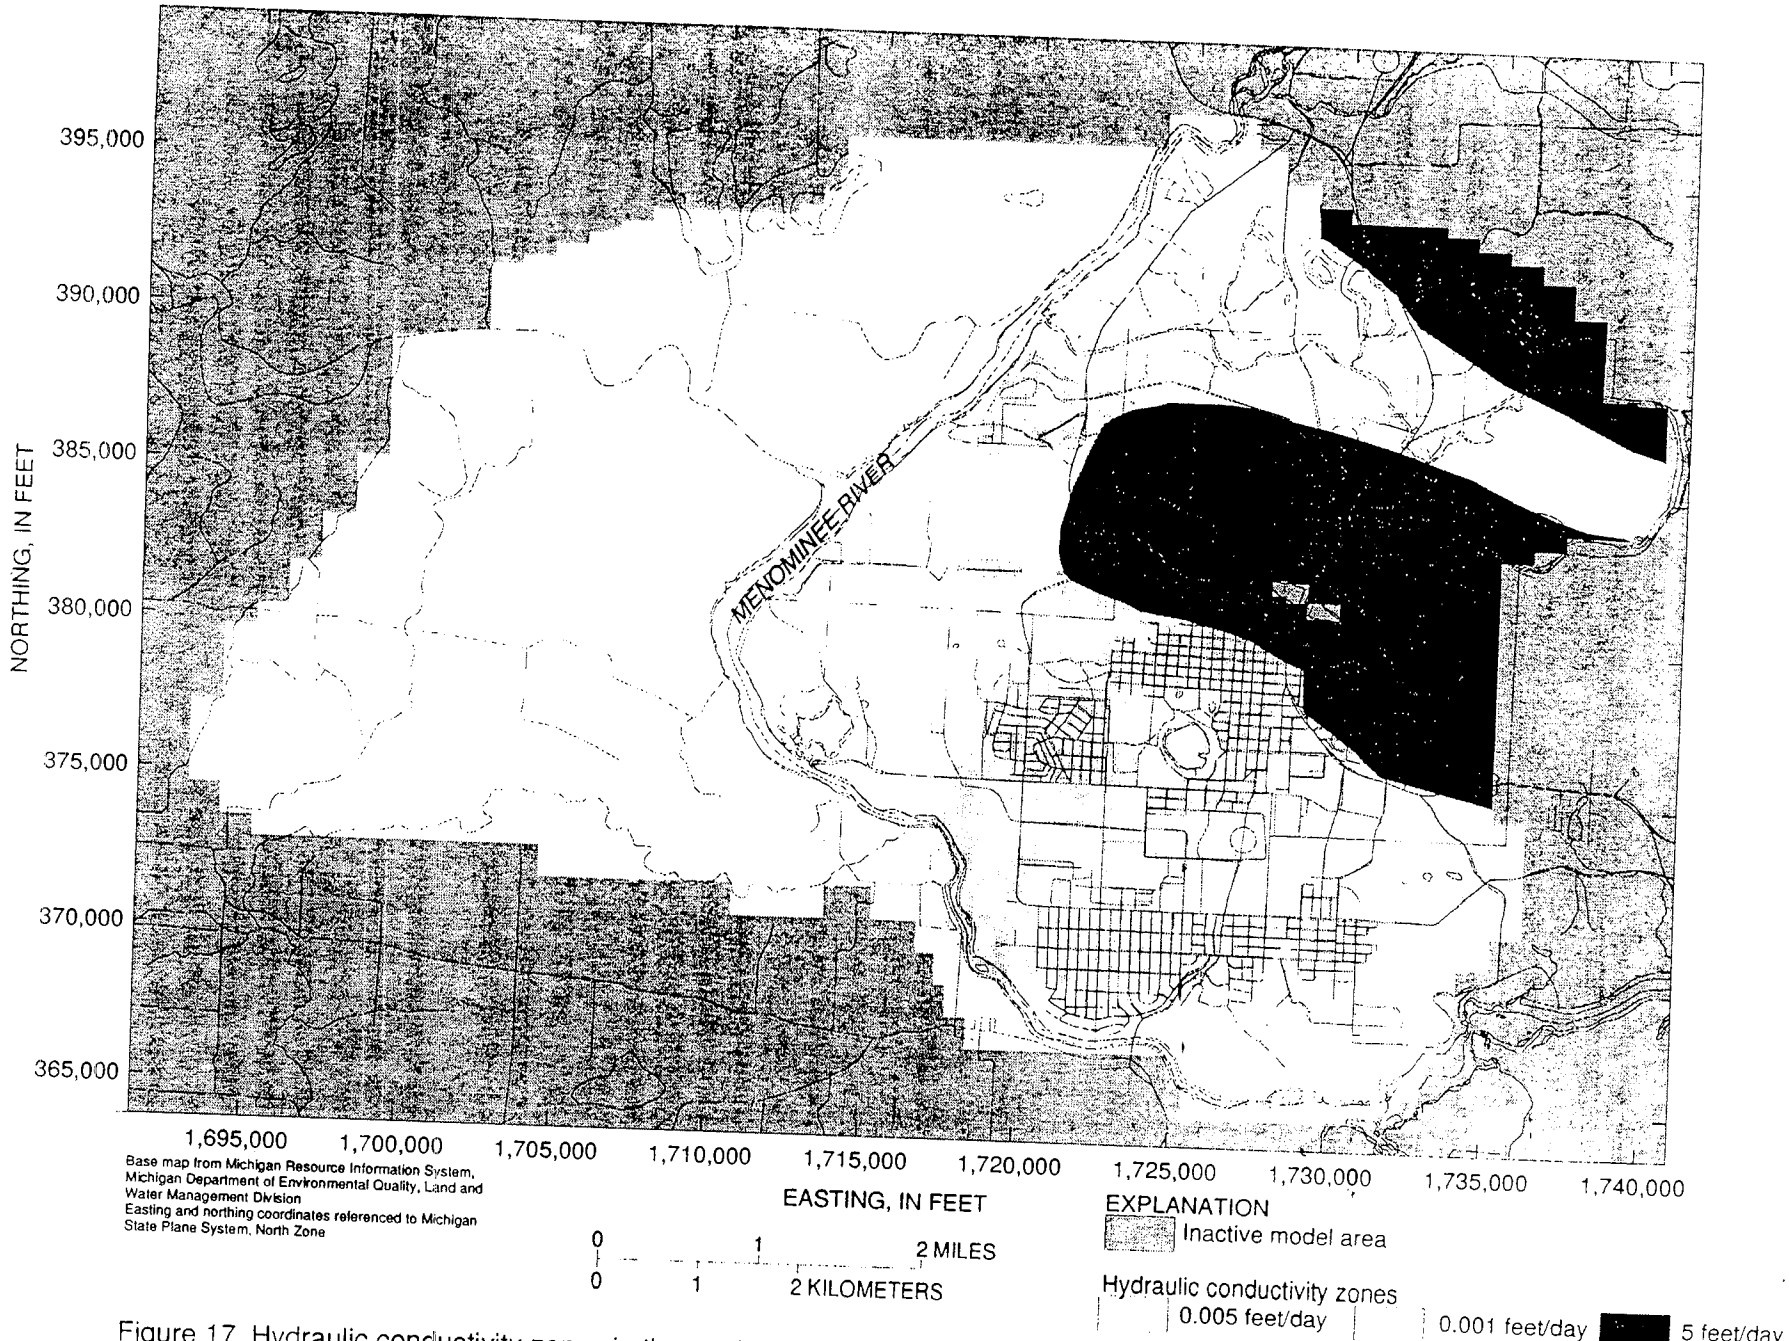

Figure 17. Hydraulic conductivity zones in the confining unit between the upper and lower aquifers (model layers 1 and 2), Kingsford-Iron Mountain area, Michigan.

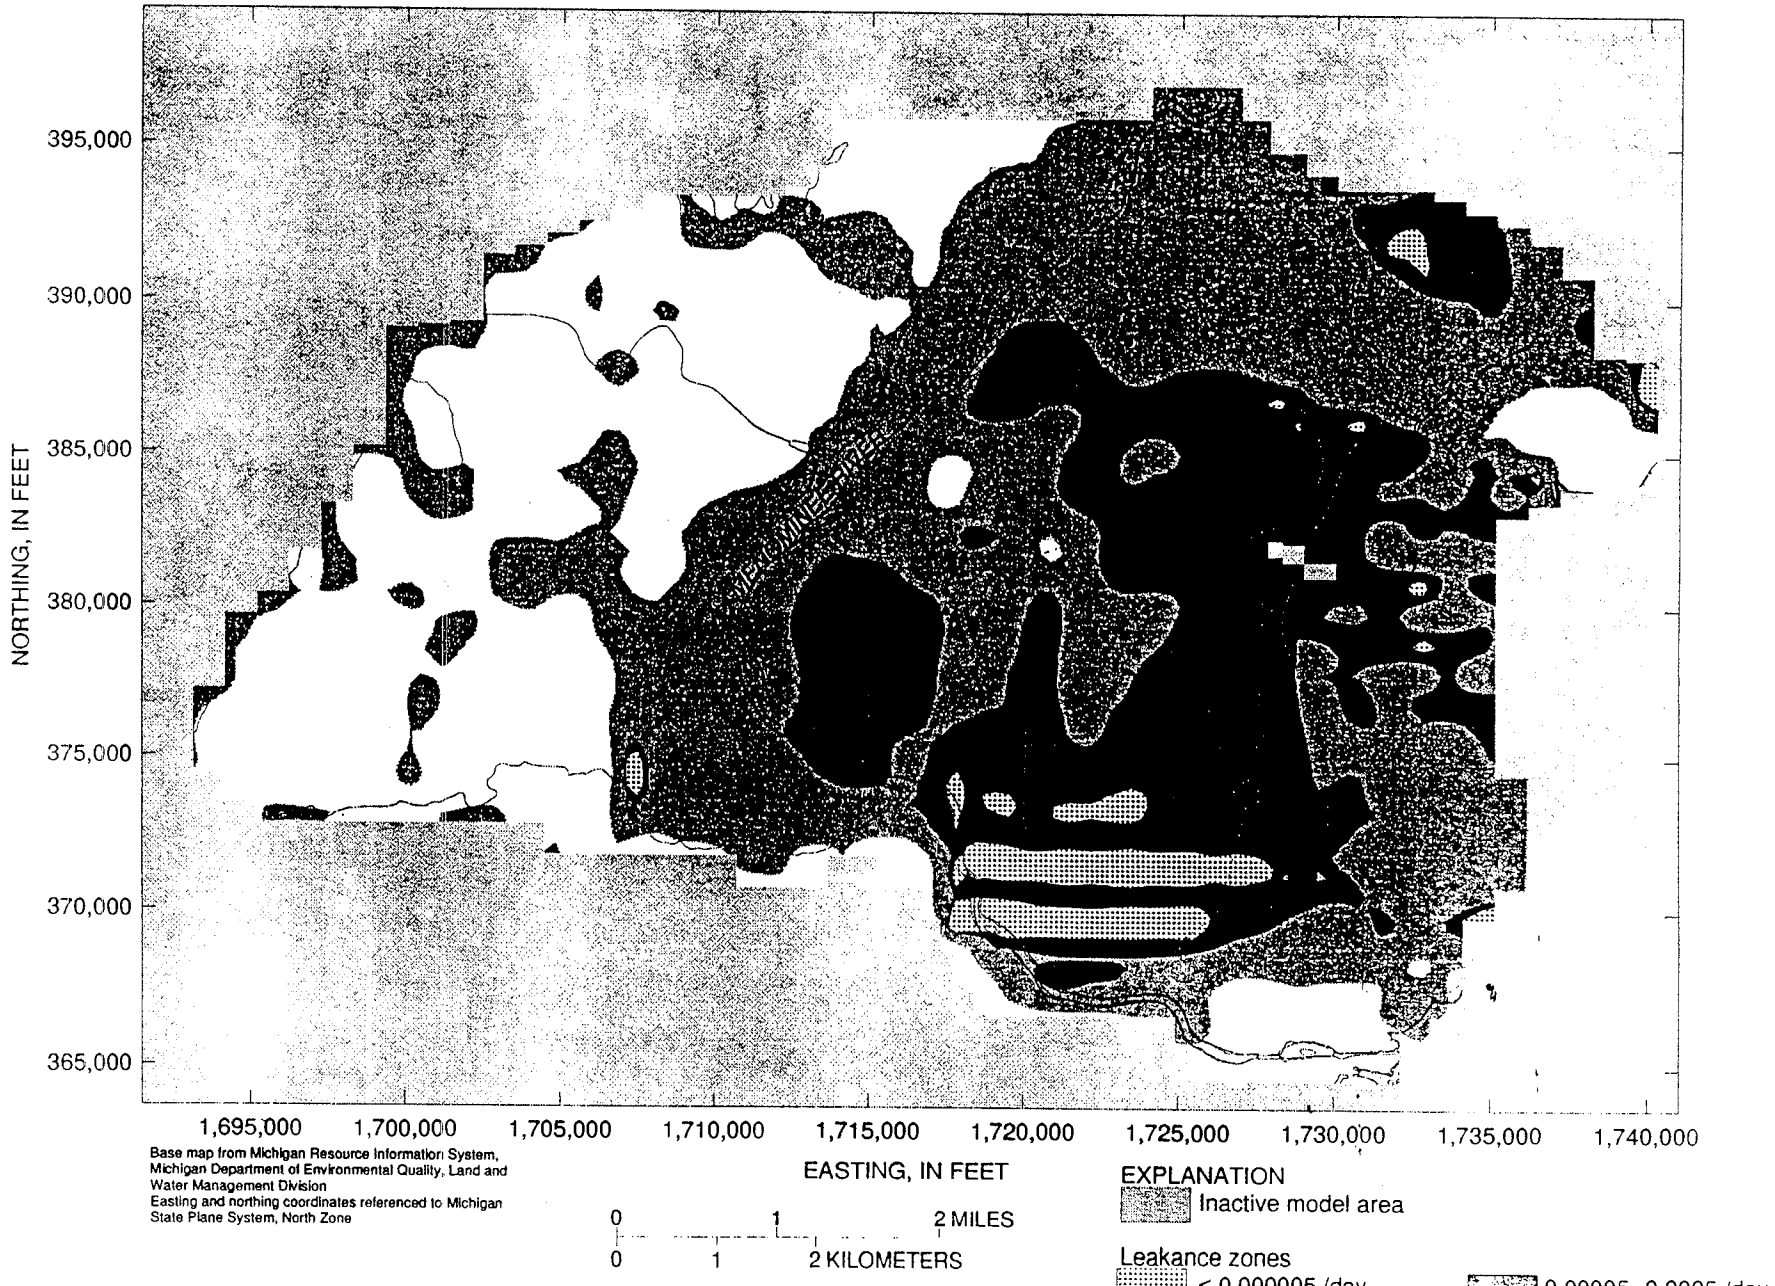

Figure 18. Estimated vertical leakance between the upper and lower aquifers (model layers 1 and 2), Kingsford-Iron Mountain area, Michigan

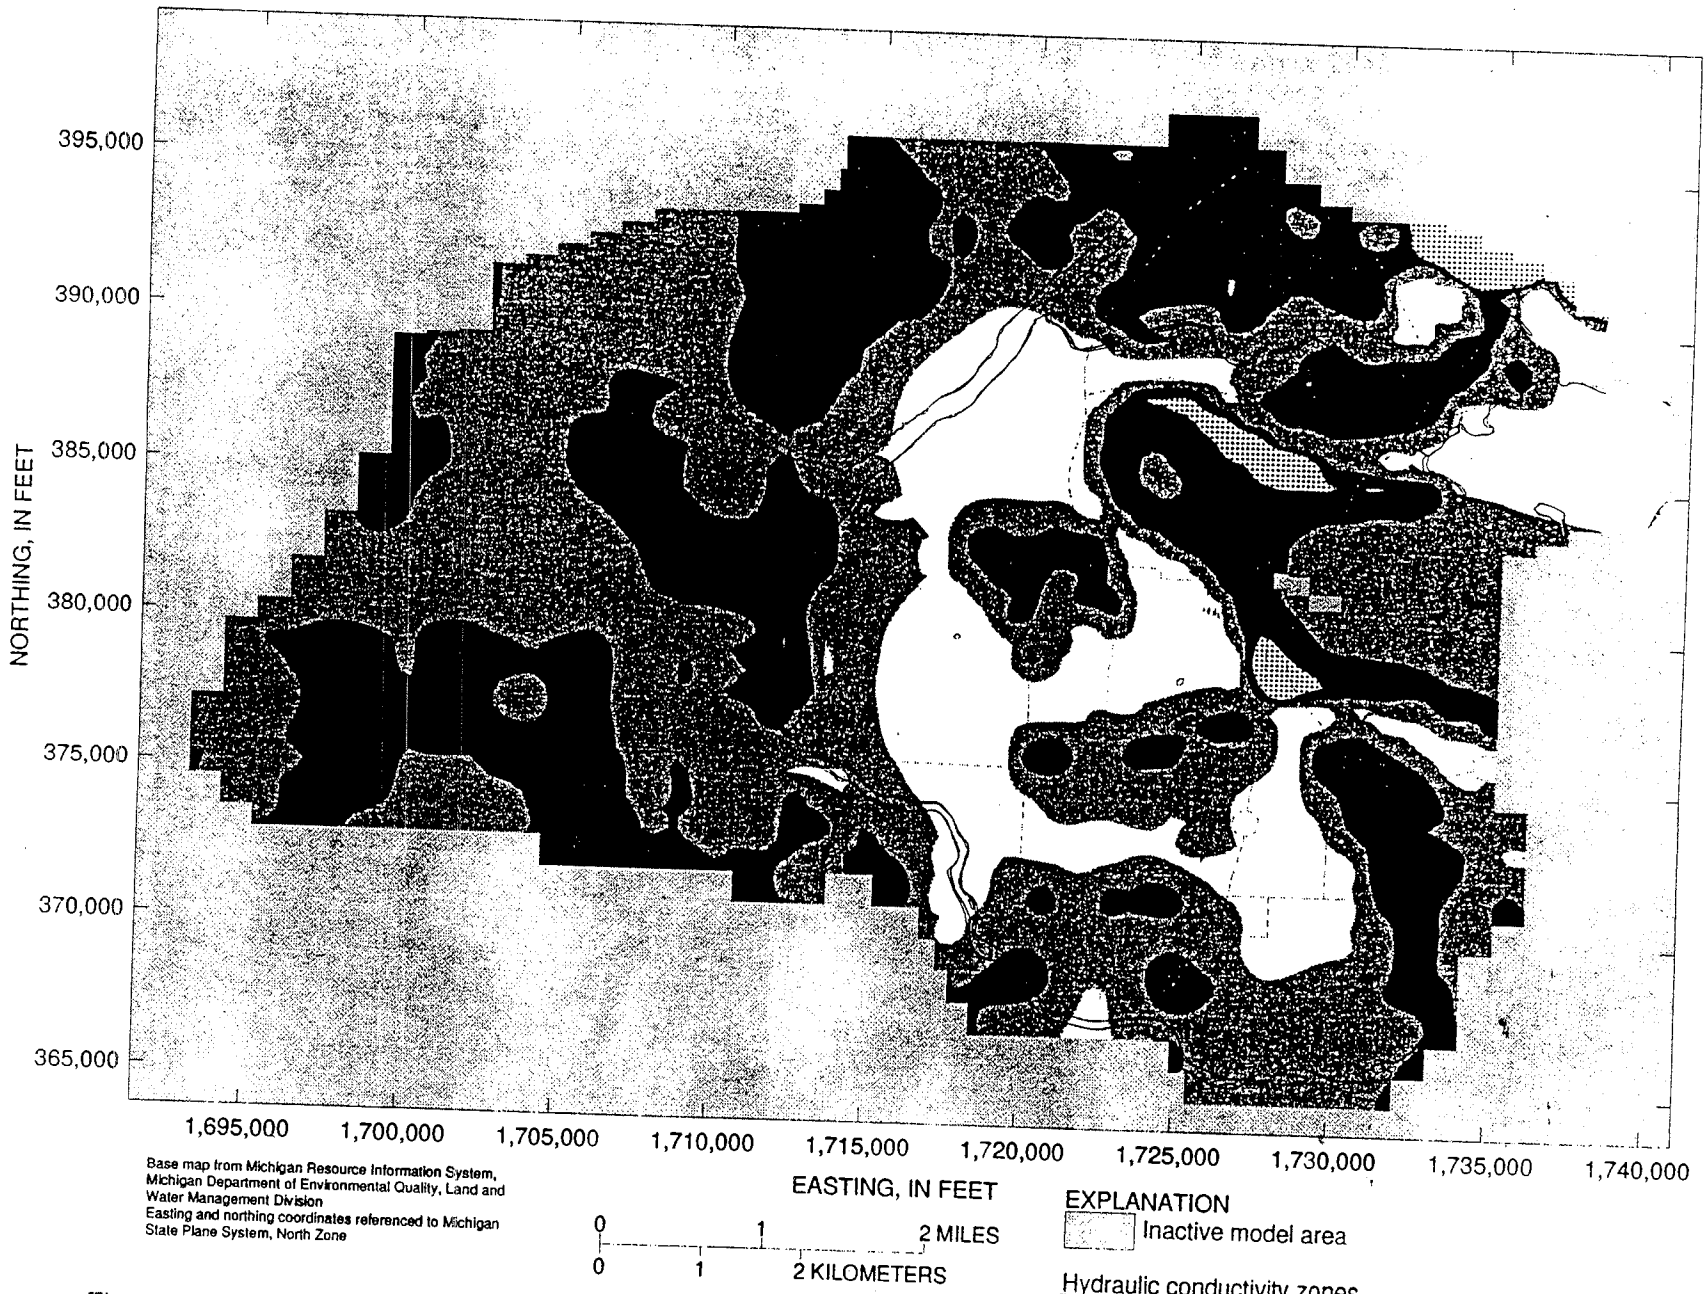

Figure 19. Estimated vertical leakance between the lower aquifer and the lodgement till-metasedimentary rocks (model layers 2 and 3), Kingsford-Iron Mountain area, Michigan

hydraulic conductivities for the lake cells were initially estimated to be 10 ft/d.

Ground-water withdrawals were simulated from the center of the cell containing a pumping well. Because of the close proximity of Iron Mountain wells 1 and 2, these wells were simulated as pumping from the same cell. Withdrawals from Kingsford and Iron Mountain wells totaled:

0.76 mgd	Iron MountainWells #1 and #2
0.14 mgd	Iron Mountain Well #3
0.32 mgd	Iron Mountain Well #4
0.15 mgd	Kingsford Well #1
0.28 mgd	Kingsford Well #5
0.23 mgd	Kingsford Well #6
0.37 mgd	Kingsford Well #7

Model Calibration

Model calibration is the process of reducing the difference between measured and simulated water levels and flows by adjusting model parameters. Multiple calibration trials were used to determine the set of parameter values that produced the best fit between simulated and measured values, whereas keeping parameters and the overall water budget within estimated values.

Head data used in the calibration of the ground-water-flow model include water-level measurements made during this study, measurements made during previous investigations of the Kingsford area, and measurements recorded on domestic well logs. Of the measurements used for this study, 24 are in layer 1, 44 are in layer 2, and 5 are in layer 3. Long-term drawdown measurements for the public-supply wells were included for comparison purposes. Because of the way in which pumping is represented in the model (continuous pumping at a constant rate, rather than intermittent pumping at varying rates); however, the water-level measurements at pumping wells will not be represented exactly.

Flow data at USGS gaging stations were examined to determine upper and lower bounds on flow within the Menominee River. Long-term data (greater than 80 years of record) are available for two stations (04063000 and 04063500) on the Menominee River upstream of the model area. Flow at these stations averaged 1,797 ft^3/s for 04063000 and 1,812 ft^3/s for 04063500 over the available years of record for similar size drainage basins (Water Resources Data for Michigan, Water Years 1996 and 1997). The length of river reach between these two stations is approximately the same length as that in the model area and the flow is assumed to be representative. The difference between these flows is small and is probably within the expected error range of the measurements; however, this comparison serves to illustrate that flow to river cells within the model is expected to be small (less than 15 ft^3/s).

Model sensitivity was investigated by varying model parameters within expected ranges (scenarios 1 – 9, Appendix) and comparing the resulting root mean square errors (RMSE). Different scenarios were considered because of the complexity of the ground-water system being represented, differing geologic materials and water levels observed at adjacent wells, the steep gradients present, and the unknown location of the water table in some areas of the model. The root mean square error is the average of the squared differences in measured and simulated water levels. RMSE values and simulated model flow budgets were compared for scenarios in which recharge to ground water; hydraulic conductivity of the streambed materials, zone 1 in layer 1, Cowboy Lake area, Iron Mountain Well #4 area, and zone 5 in layer 2, and all zones in layer 3; and the leakances between layers were varied. The best fit between measured

and simulated water levels was achieved when the Menominee River was represented as specified head cells in both layers 1 and 2 (scenario 1); however, this representation of the river does not allow for the possibility of flow beneath the river which was investigated in other scenarios (appendix).

The final parameter estimates (scenario 4) for each zone are within reasonable ranges (table 3).

Table 3. Final horizontal hydraulic conductivity estimates for layer zones in the ground-water-flow model for the Kingsford-Iron Mountain area, Michigan

3	9	.1
	10	.01
	11	.001

The horizontal hydraulic conductivities of layer zones are within the ranges determined from aquifer tests and flow to river cells is within the expected order of magnitude. Flow to river cells increased and water levels in layer 1 were higher with an increase in recharge. Recharge of 2 in/yr to till areas did not change the extent of the unsaturated areas and water levels remained about the same in all layers. Water levels in layer 1 were lower with increases in hydraulic conductivity for layer 1 or 2. Water levels in layer 2 remained about the same with an increase in the hydraulic conductivity of layer 1 and decreased with an increase in the hydraulic conductivity of layer 2. Water levels remained about the same with changes in the hydraulic conductivity of layer 3. Water levels were higher in layer 1 and remained about the same in layer 2 with changes in streambed hydraulic conductivity; however, flow to river cells decreased with lower streambed conductivity and increased with higher streambed conductivity. Changes in leakance resulted in small changes in water levels.

Results of model simulations indicate close agreement between water flowing into and out of the model area; percent discrepancy equalled –0.49 (table 4). Generally simulated water levels are close to measured water levels with the residuals about evenly split above and below the line representing simulated equal to measured water levels (fig. 20a, b, and c). Seventy-one percent of the simulated water levels are within 15 ft of the measured values. Differences between simulated and measured values are shown in figure 21 and do not indicate any spatial trends. Simulated water levels for layers 1 and 2 are shown in figures 22 and 23, respectively. Part of the difficulty in matching measured values is due to large observed differences in nearby wells. The simulated streamflow of 9.6 ft^3/s is less than 15 ft^3/s as expected. The simulated values obtained represent the best match to these different values.

Table 4. Ground-water-flow model budget, Kingsford-Iron Mountain area, Michigan

Budget component	Rate (cubic feet per day)
FLOW INTO MODEL AREA:	
Constant head	2,095,436.0
Recharge	1,504,997.0
River leakage	134,108.2
FLOW OUT OF MODEL AREA:	
Constant head	2,488,620.0
Wells	300,935.0
River leakage	963,167.3

Investigation of Boundary Effects

Choice of hydraulic boundaries (such as the specified heads used in this model) does not allow conditions along the boundaries to change from initial values; thus, one must investigate whether the boundaries are affecting the solution in the interior portion of the model (Anderson and Woessner, 1992). After selection of a final model, changes in conditions at boundaries were investigated by comparing flow through specified head cells forming boundaries for simulations in which wells were pumping and in which wells were idle. Flow through the individual specified head cells when the public-supply wells were pumping differed by an average of 2.6 percent (standard deviation equaled 23.8) from the flow through these same cells when the public-supply wells were simulated as idle. As an additional check on the boundaries, specified head cells were changed to specified flow cells using the well package to represent the specified flows. The ground-water-flow solution differed slightly near the edge of the dry cell area when the specified heads were changed to specified flows. Water-level differences between the two solutions at measurement locations were within 2 ft or less. Stresses induced from pumping by the public-supply wells only affected water levels locally and did not affect flow across streamlines.

Model Limitations

The ground-water-flow model was developed to simulate the regional steady-state response of the flow system in the Kingsford-Iron Mountain area to ground-water withdrawals by the public-supply wells. Hydraulic properties in the aquifers were assumed to be isotropic. (Within a cell hydraulic properties are the same in the north-south direction as in the east-west direction; hydraulic properties vary from location to location). Vertical variations in aquifer properties within layers and any variations in head or flow within the aquifers are not represented in the model. Model simulations are restricted to steady-state conditions. All stresses within and inputs to the system, including well withdrawals and recharge rates, remain constant throughout the simulation. No net gain or loss of flow is simulated in the system and no changes in ground-water storage occur. This model, in its current (2000) form, cannot be used to simulate transient-flow conditions.

Each grid cell represents the average hydrologic and hydraulic properties in the volume of aquifer represented by the cell, and any variations in properties within the volume represented by the grid cell cannot be represented. Local flows over distances smaller than the dimensions of the grid cell also cannot be accurately represented. Additional geologic and hydrologic data, as well as finer discretization of the model, would be needed to simulate smaller-scale flow systems. Hydraulic properties of the individual layers are represented by zones and local variations are not represented. This representation by zones generalizes the glacial and bedrock properties and small-scale differences in ground-water flows are not represented. This generalization was necessary because nearby wells often penetrate different lithologic units with varying thicknesses and detailed geologic information is unavailable for large portions of the model area. The accuracy of layer surfaces and hydraulic conductivity estimates are limited by the available data at well and boring locations. Additional control and accuracy could be achieved by inclusion of more data points.

Recharge to ground water was assumed to vary over the model area depending on the presence or absence of surficial till deposits and poorly permeable

bedrock; thus, local variations in recharge rates, such as those associated with impermeable surfaces or differences in other types of surficial materials, are not represented in the model. Recharge in areas of surficial till deposits is assumed to be negligible. Simulated well withdrawals are assumed to come from the centers of grid cells. Small withdrawals from domestic wells were not included because of the difficulty in obtaining reliable data and the limitations in representing small-scale flow systems. However, domestic ground-water withdrawals are probably small at the scale of the model.

Other than flow within the Precambrian metasedimentary bedrock units in the vicinity of Pine Mountain and Millie Hill, the model does not simulate flow within the bedrock units. Thus, the bottom of the model is considered to be impermeable. This assumption is considered adequate for model development because of the limited flow available from fractures in bedrock. The model does not simulate flow through fractures or fissures in the rocks. Primary and secondary porosities are combined to represent average flow conditions. Thus, the presence of fractures and fissures could create local heterogeneities in hydraulic properties, which can not be represented by the model.

External boundary conditions were based on natural hydrologic conditions and were located distant from Kingsford's and Iron Mountain's well fields, and, based on the investigation of flow through the specified head cells, are assumed to have minimal effect on the solution in the interior portion of the model. Enlargement of the model area to natural physical hydrologic boundaries might improve model simulations and convergence and improve the match between simulated and observed ground water flows.

Different scenarios (in which recharge, hydraulic conductivity, and leakance parameters were varied) were considered because of the complexity of the system, different lithologic units and water levels observed at nearby wells, the steep gradients present, and the unknown location of the water table in some parts of the model area. Cells that went dry during model simulations were permitted to rewet; however, most remained dry. Most of the dry cells were in the vicinity of Pine Mountain, Millie Hill, and Trader Hill. In these areas the glacial deposits are thin and unsaturated. The measured water level in a well drilled on top of Pine Mountain shows that glacial deposits and bedrock are dry to the base of the mountain.

The accuracy of particle-tracking simulations is limited by the accuracy of the numerical model on which the simulations are based, the estimates of the effective porosity of the flow system, and the approximation of the cell flow velocities to the local ground-water-flow velocities. Additionally, the particle-tracking program considers ground-water flow by advection only. If the effects of dispersion were included, the contributing areas could be larger. Because the model does not specifically describe flow through fractures, ground-water flow and travel times in areas where fractures are present may not be accurately represented. Particle tracking was performed for public-supply wells near the center of the model area. Detailed analysis of contributing areas for small localized areas is inappropriate because the model was not designed to represent local flow systems. The areas that are represented as being dry in model simulations may contribute water and contaminants, if present, to the public-supply wells.

DELINEATION OF CONTRIBUTING AREAS

The particle-tracking program MODPATH (Pollock, 1989) can be combined with MODFLOW-calculated flow in each cell

to determine areas contributing water to public-supply wells. In this study, the particle-tracking program was used by specifying the locations of hypothetical water particles along the faces of each cell containing a public-supply well. These particles then were tracked backward in time through the ground-water-flow system until they reached the top cell face in layer 1, which represents the starting location of the particle. This collection of starting locations, projected up to the land surface, represents the contributing areas for the public-supply wells. The subsurface zones through which the particles travel are known as the zone of transport. Particles also can be tracked for a specified amount of time, such as 10 years. This 10 year time-of-travel area is identified by those particles whose travel times are 10 years or less. An estimated effective porosity of 15 percent was used in the delineation for all layers. This value is less than the estimated total porosity of 25 percent, which is representative of these types of materials (Freeze and Cherry, 1996) and provides a conservative estimate of the contributing areas. Particle tracking results were compared for several of the scenarios and found to delineate similar areas.

Particle tracking describes the advective movement of ground water and does not incorporate the effects of adsorption, diffusion, dispersion, and degradation. Therefore, particle tracking is not intended as a substitute for modeling transport of dissolved chemicals in a ground-water system.

The 10-year contributing areas for Kingsford's public-supply wells encompass about 0.11 mi^2, or 302 model cells, and consist of elongated areas to the east of the well fields (fig. 24). The 10-year contributing areas for Iron Mountain's public-supply wells encompass about 0.09 mi^2, or 30 model cells, and consist of elongated areas to the east of the well field. The 10-year zone-of-transport consist of elongated zones east and west of the well fields. Actual contributing areas may be larger because the areas that are represented as being dry in model simulations may contribute water and contaminants, if present, to the public-supply wells. Forty year time-of-travel contributing areas are shown in figure 25.

SUMMARY

A ground-water-flow model was developed to simulate the regional, steady-state ground-water flow system in the Kingsford-Iron Mountain area. Kingsford and Iron Mountain are located in Dickinson County in the Upper Peninsula of Michigan. These two cities rely entirely on ground water withdrawn for public supply from the glacial deposits. The glacial deposits overlie Precambrian metasedimentary (Michigamme Slate, Vulcan Iron Formation, and Randville Dolomite) and metavolcanic (Badwater Greenstone) rocks, except along the Menominee River and in isolated areas where bedrock is exposed. Glacial deposits range from 0 to about 380 ft in thickness.

Two glacial sand-and-gravel aquifers are present in the study area. The upper aquifer ranges from 0 to 160 ft in thickness and consists of medium to fine grained sand with varying amounts of silt and gravel. The confining unit ranges from 0 to 150 ft in thickness and consists of well sorted and well compacted fine silt with clay. In some areas the silt and clay are absent due to partial burial and protrusion of stranded ice blocks that prevented silt deposition. The intermediate silt layer is a fairly effective barrier to hydraulic communication between the two aquifers. However, where the silt is absent in the Kingsford area, the two aquifers appear to be hydraulically connected. The lower aquifer ranges from 0 to 237 ft in thickness and consists of moderately well sorted fine to coarse sand with layers and

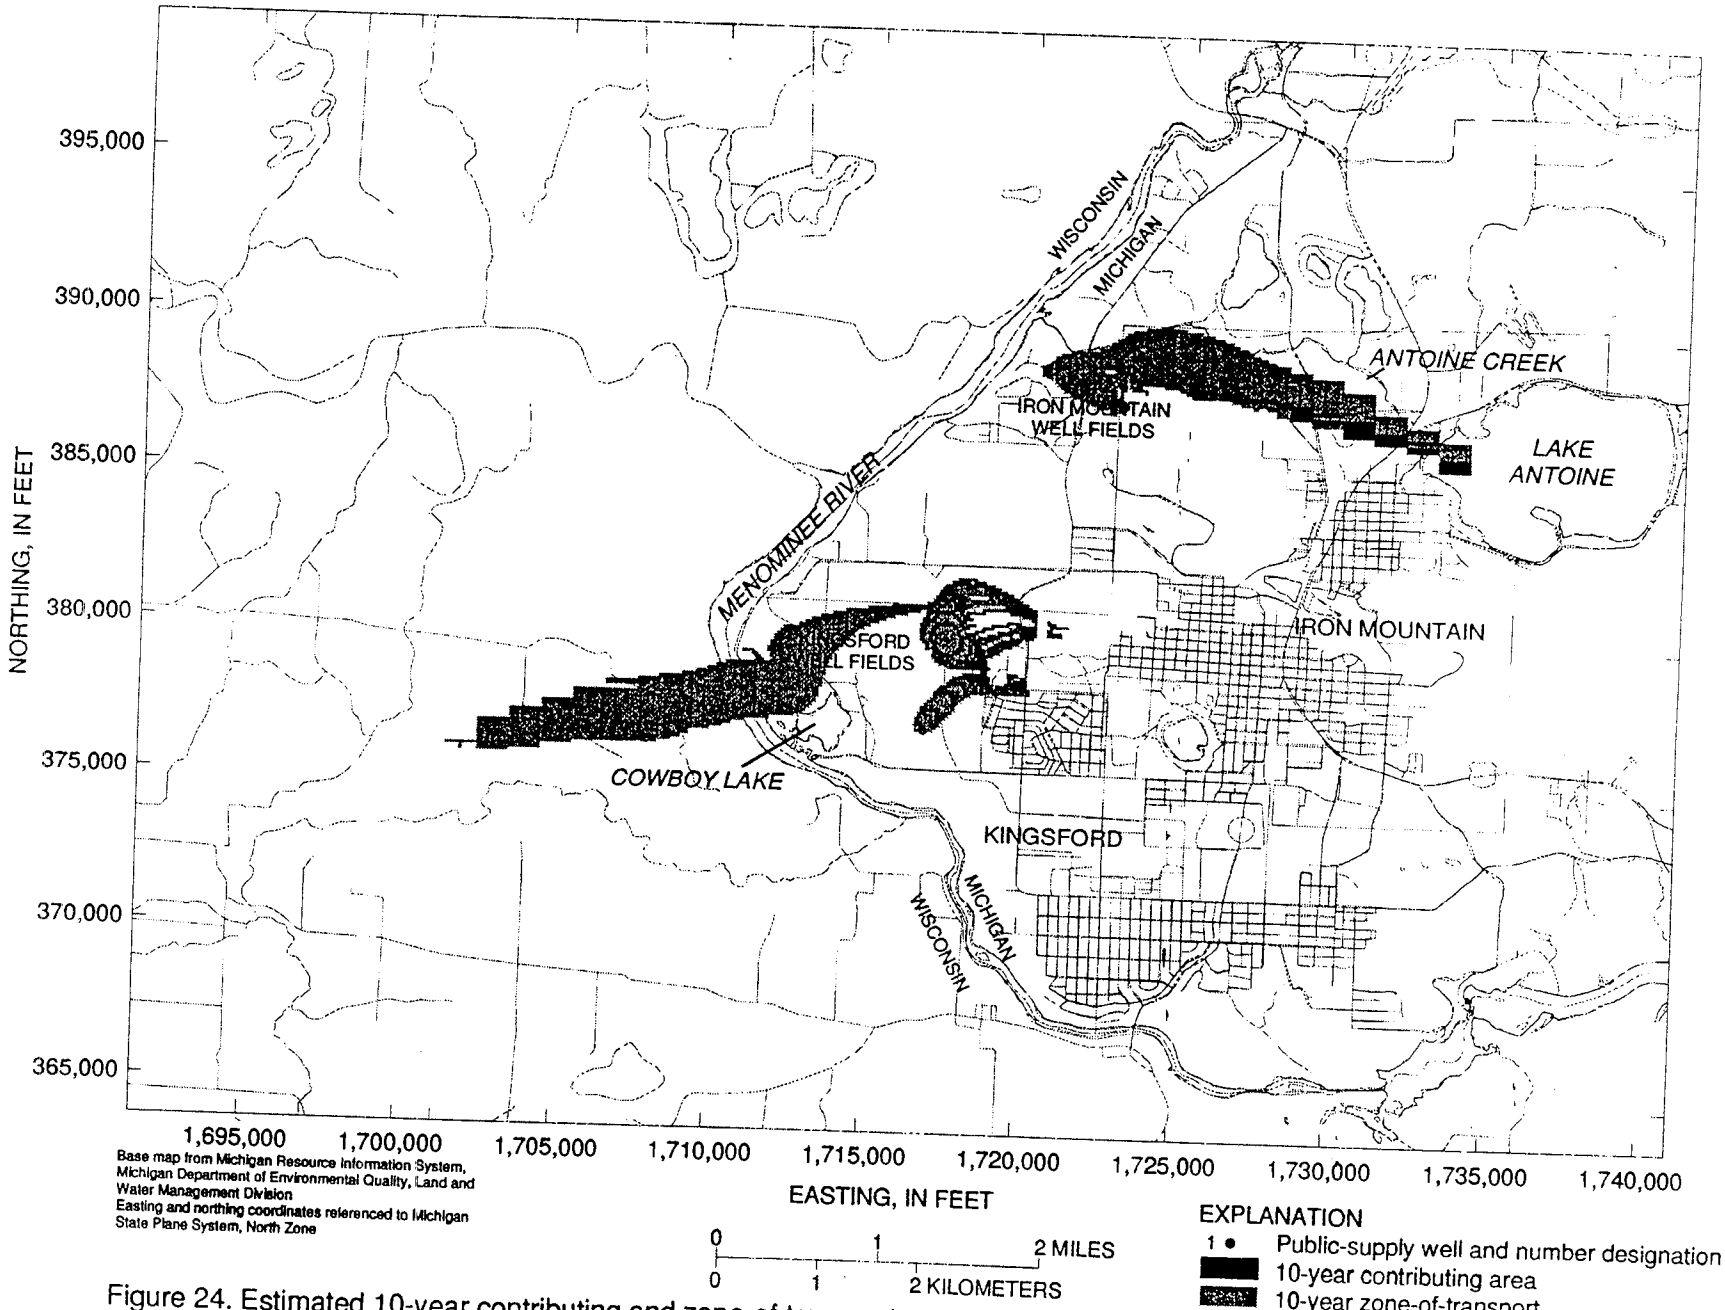

Figure 24. Estimated 10-year contributing and zone-of-transport areas projected to the land surface in the Kingsford-Iron Mountain area, Michigan.

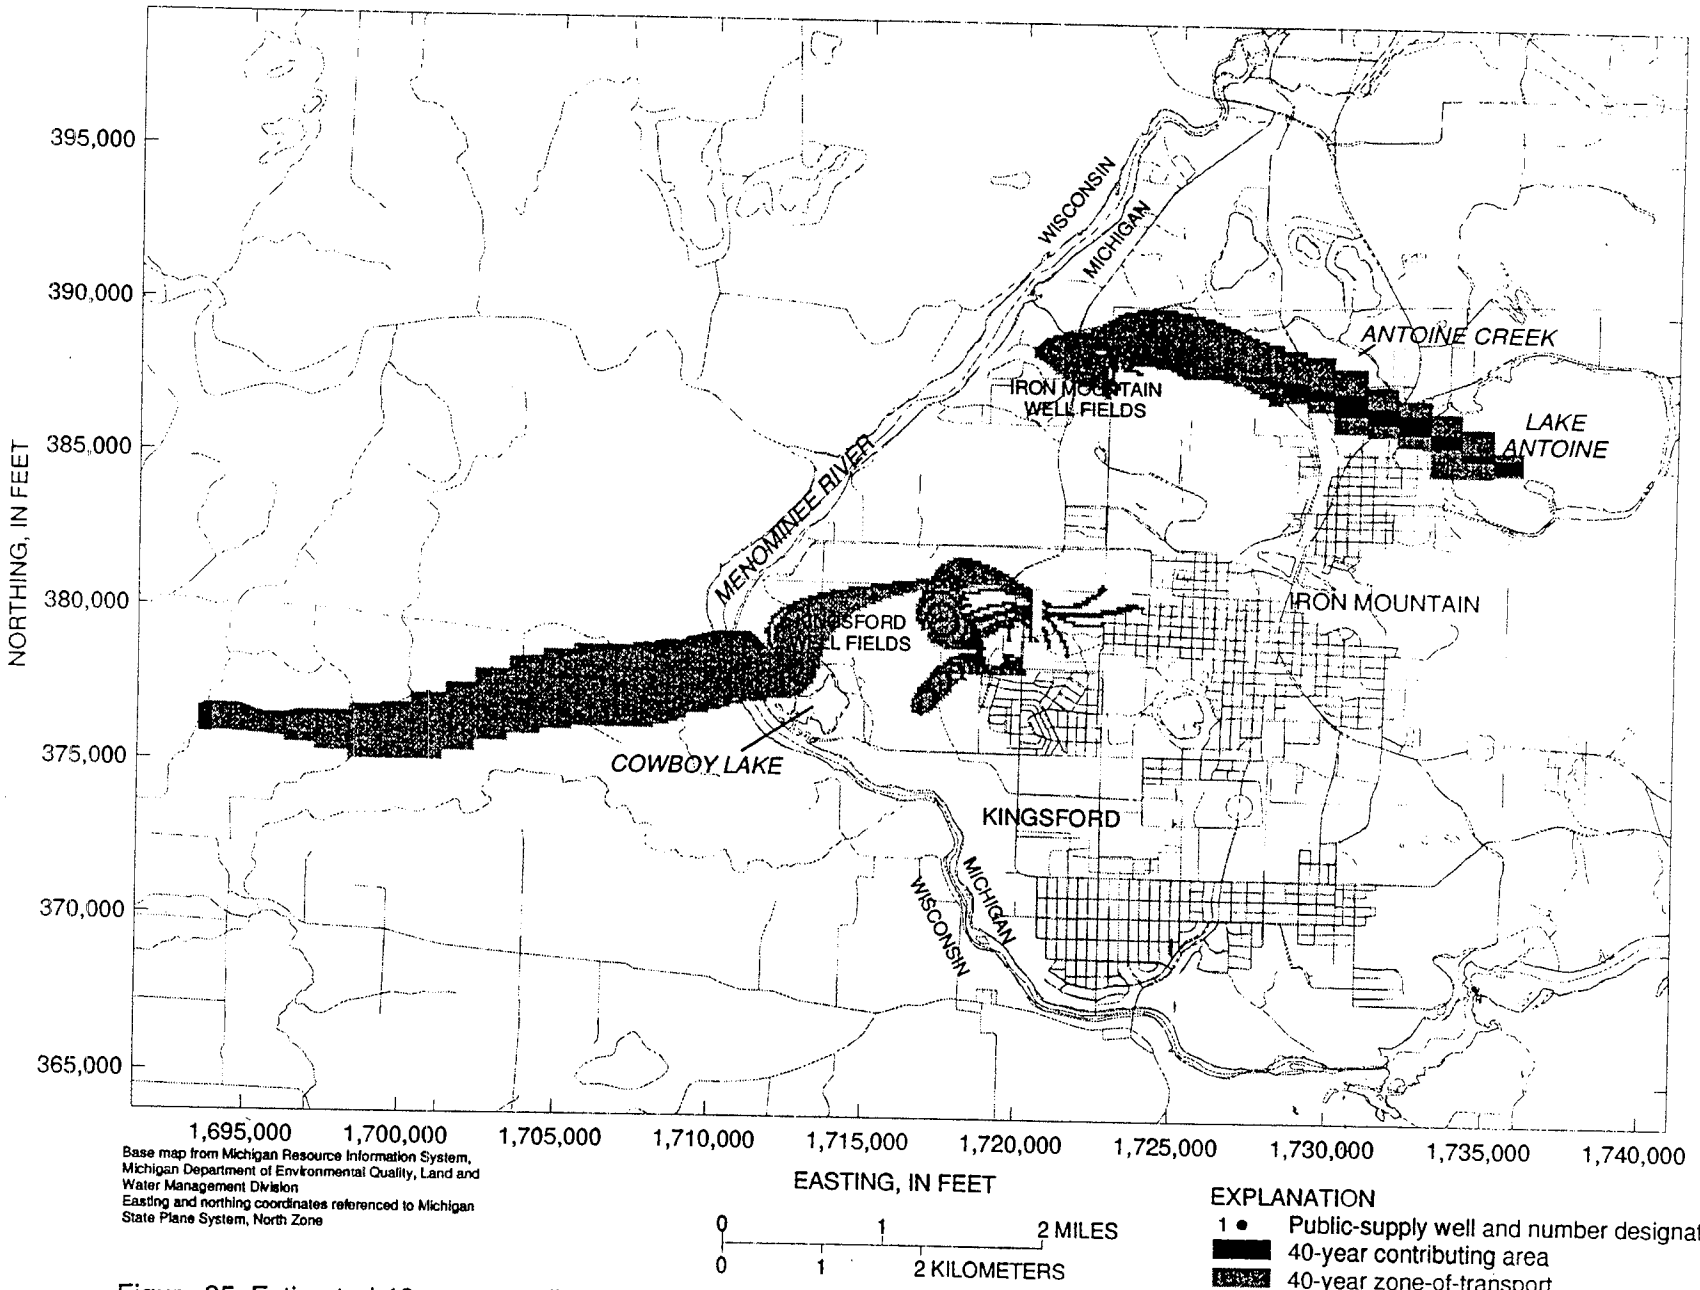

Figure 25. Estimated 40-year contributing and zone-of-transport areas projected to the land surface in the Kingsford-Iron Mountain area, Michigan.

lenses of silt. The lodgement till unit ranges from 0 to 25 ft in thickness.

Ground-water flow within glacial deposits in the Kingsford-Iron Mountain area is primarily towards surface-water bodies to the west and southwest and follows the regional topographic slope and bedrock surface. Ground-water flow is probably confined primarily within the permeable sand-and-gravel units because the Precambrian bedrock units appear to be largely unfractured and limit the downward migration of ground water. However, bedrock consists of metasedimentary bedrock units in the vicinity of Pine Mountain, and ground-water flow is locally affected by these units where they are fractured.

The ground-water-flow model developed for the Kingsford-Iron Mountain area encompasses part of Dickinson County, Michigan and Florence County, Wisconsin. This area is horizontally discretized into a variably spaced grid of cells in 213 columns and 204 rows. The model area is vertically discretized into three model layers. Layer 1 represents the upper aquifer in the glacial deposits; layer 2 represents the lower aquifer in the glacial deposits; and layer 3 represents either lodgement till or metasedimentary bedrock units where they are present in the model area. The intermediate confining unit between the upper and lower glacial aquifers is included only in the leakance term between layers 1 and 2. Specified-head, specified flux, and head-dependent flux cells form the model boundaries.

Conceptualized estimates of hydraulic conductivity for each layer were based on aquifer tests and on representative values taken from Freeze and Cherry (1979). These estimates were modified during model calibration. Each of the three layers was divided into zones containing similar geologic materials based on interpretation of well and geophysical logs.

The model was calibrated using multiple trials where parameters were changed to reduce differences between simulated and observed values, and to keep parameter estimates and the overall model budget within reasonable limits. Differences between observed and simulated values are attributed to the complex geology and hydrology of this area, the steep gradients in the vicinities of Pine Mountain, Millie Hill, and Trader Hill, and the large areas in which detailed hydrogeologic information was unavailable. Different scenarios (in which recharge, hydraulic conductivity, and leakance parameters were varied) were simulated in order to verify the reproducibility of regional ground-water-flow directions and contributing areas.

Contributing areas were delineated for Kingsford's and Iron Mountain's public-supply wells using particle-tracking analysis. Results of flow simulations based on 1997-1998 pumping conditions indicate that 10-year contributing areas, delineated by those particles with travel times of 10 years or less, cover 0.2 mi^2.

Appendix B

Hydrogeologic Framework, Areas Exceeding Acute GSI Criteria, and Results of Aquifer Pumping Tests Performed in the Vicinity of the Menominee River

ARCADIS

APPENDIX B

Hydrogeologic Framework, Areas Exceeding Acute GSI Criteria, and Results of Aquifer Pumping Tests Performed in the Vicinity of the Menominee River

Introduction

ARCADIS, on behalf of Ford Motor Company (Ford) and The Kingsford Products Company (KPC) performed a multiphase pilot study along the Menominee River in Kingsford, Michigan to understand hydraulic and groundwater quality responses to groundwater extraction. The hydraulic data obtained from groundwater pumping tests that were performed during the pilot study were used in developing a groundwater flow model for the Ford/Kingsford Site (Site). Presented in this document is the hydrogeologic framework in the vicinity of the Menominee River, the areas where groundwater quality exceeds the acute groundwater surface water interface (GSI) criteria, and the hydraulic properties of the groundwater system based on the analysis of pumping tests conducted on extraction wells installed on the east side of the Menominee River.

Some of the hydraulic properties of the groundwater system were presented in documents previously submitted to the Michigan Department of Environmental Quality (MDEQ), which contained a detailed analysis of the aquifer pumping tests that were performed. During the fall of 2003 additional aquifer pumping tests were conducted on existing and newly installed extraction wells. This document contains only a summary of the results of the previous pumping tests, which have already been documented. Analysis of pumping tests that were performed in the fall of 2003, which have previously not been documented, is presented in this document.

Hydrogeologic Setting

Study Area

The local geologic system is comprised of glacially derived unconsolidated deposits consisting of clay, silt, sand, and gravel that overlie bedrock. This geologic system is complex, with the deposits having lateral and vertical spatial variability. This variability is consistent with the glacial depositional environments that formed these deposits. The data points that were used to derive the geologic setting in the study area are shown in Figure B-1, which shows the locations of monitoring wells, soil borings, piezometers and soil vapor probes. The depth to the bedrock (or the thickness of the unconsolidated deposits) is up to 363 feet in the center of the study area. In the area adjacent to the Menominee River, where aquifer pumping tests have been conducted, the bedrock ranges in depth from about 110 feet below land surface (ft bls) to over 220 ft bls.

The various lithologic formations, deposited under glaciolacustrine and glaciofluvial conditions, can be characterized by three composite units, which represent hydrogeologic units and characterize depositional settings. These three composite units are categorized as Unit 1 (fine-grain to coarse-grain sand and gravel), Unit 2 (very fine-grain sand and silty sand/sandy silt), and Unit 3 (silt and clay). The hydraulic conductivities in the coarser-grain sand units (Unit 1) generally range from approximately 10^{-3} centimeters per second (cm/sec) to 10^{-1} cm/sec. Well development records show that most of the

monitoring wells completed in the sand units produce sediment free water and can sustain flow rates over 1 gallon per minute (gpm) with little water level drawdown.

The hydraulic conductivities in Unit 2, which is characterized by very fine-grain sand and silty sand/sandy silt, range from 1×10^{-3} cm/sec to 4×10^{-5} cm/sec. As a result of the hydraulic conditions, only a few monitoring wells were screened in this type of unit because of the difficulty in producing groundwater from this unit. Monitoring wells in this unit can be purged dry and produce significant amounts of silt even after these wells are developed.

Data are not available for the hydraulic properties of the silt and clay, which are considered Unit 3, because aquifer tests were not performed in this unit. However the silt and clay representative of Unit 3 are expected to have hydraulic conductivities that are an order of magnitude or more lower then those determined for Unit 2.

The groundwater system at the Study Area is also complex. Different zones within the groundwater system are hydraulically connected; however, the varying hydraulic properties of the different zones result in preferred pathways for groundwater movement. These preferred pathways in the groundwater flow system consist of the higher permeability Unit 1 (sand and gravel) that are inner lain with lower permeability Units 2 and 3 (very fine-grain sand, silty sand/sandy silt, silt, and clay).

Vicinity of the Menominee River

Detailed subsurface investigations have been conducted in the vicinity of the Menominee River to identify preferential groundwater pathways (Unit 1), which were documented in the Remedial Investigation (RI) Report dated June 2002. Since submittal of the RI Report, additional subsurface investigations have been conducted on the eastern side of the Menominee River. These investigations were conducted to better understand groundwater conditions on the eastern side of the Menominee River and to be able to delineate areas where groundwater quality exceeds GSI criteria. Between August and December 2003, eight soil borings (Soil Borings GMSB-111, GMSB-112, GMSB-113, GMSB-116, GMSB-117, GMSB-118, GMSB-119, GMSB-122), three monitoring wells (Monitoring Wells GM-77, GM-78, GM-79), three extraction wells (Extraction Wells GMEW-7, GMEW-8, GMEW-9), and four piezometers (Piezometers GMPZ-7, GMPZ-8, GMPZ-9, GMPZ-10) were installed using hollow-stem or rotosonic drilling methods. The locations of each of these are also shown on Figure B-1. Attachment A to this appendix contains the sample/core logs and stratigraphic logs for each location noted above.

Subsurface investigations performed in the immediate vicinity of the Menominee River were used to define groundwater pathways at this location. Based on the data collected, four preferred groundwater pathways within the groundwater system have been delineated, and designated as Zone A, B, C, and D sands ranging from shallow to deep, respectively. In places some of these sand zones are absent and can also be interconnected. The Zone A, B, C and D sands are identified in a north-south hydrogeologic cross section constructed from geologic data collected during the investigations. Figure B-2 shows the location of the north-south cross section, which is shown as Figure B-3. Inspection of Figure B-3 reveals the following:

- Zone A sands are continuous along this section of the Menominee River and occur from a depth of about 5 ft bls to 50 ft bls.

- Zone B sands are discontinuous along this section of the Menominee River and generally occur between a depth of about 95 ft bls to 120 ft bls. To the north, Zone B sands pinch out between

Monitoring Well GM-25B and Soil Boring GMSB-113. To the south Zone B sands pinch out at Soil Boring GMSB-112 and reappear between Soil Boring GMSB-118 and Monitoring Well GM-26B.

- Zone C sands occur between depths of about 100 ft bls to 180 ft bls and are continuous along this section of the Menominee River, except were truncated against bedrock highs. Two bedrock highs have been identified in this area of the Menominee River, including one location at Soil Boring GMSB-118 and one location at Monitoring Well GM-63.

- Zone D sands occur on top of or near the bedrock, and where present are found at depths between approximately 185 ft bls to 220 ft bls.

To gain an insight into the distribution of these sands and intervening confining layers beneath the Menominee River a west-east hydrogeologic cross section was prepared and is presented in Figure B-4 (see Figure B-2 for location of the west-east cross section). As can be seen, at the location of Monitoring Well GM-10 on the west side of the river, there is a thicker sequence of sand between approximately 35 ft bls to 155 ft bls, which contains a silty layer from approximately 85 ft bls to110 ft bls. The data collected from Monitoring Well GM-10 suggests that the geologic deposits beneath the Menominee River in this area likely contain more sand and less silt than the geologic deposits east of the river.

Acute GSI Criteria Exceedance

Groundwater samples collected from monitoring wells installed in the immediate vicinity of the Menominee River were analyzed for site-specific constituents (target compound list) and compared to the Michigan final acute value criteria. In addition, groundwater samples were also collected from these wells for Whole Effluent Toxicity test analysis, and the results compared to the Michigan acute criteria of TUa>1. Together these criteria are used by the MDEQ to define where an exceedance of the acute GSI criteria occurs. Based on the analytical results of the groundwater samples, areas where the groundwater quality in the Zone A, B, C and D sands exceed the acute GSI criteria were delineated. These areas are shown in Figure B-5. As can be seen in Figure B-5 the groundwater quality exceeding the acute GSI criteria generally occurs in the following areas:

- Zone A sands – between Monitoring Wells GM-78 and GM-79.
- Zone B sands – between Soil Borings GMSB-112 and GMSB-113.
- Zone C sands – between Monitoring Wells GM-66A/B and GM-63A/B.
- Zone D sands – there are no exceedances of acute GSI criteria.

Summary of Hydraulic Properties from Previous Pumping Tests

During the multiphase groundwater pilot study, a number of pumping tests on extraction wells were performed to understand groundwater level responses from groundwater extraction. Hydraulic properties for the groundwater system were derived from these responses and these data were incorporated into a groundwater flow model developed for the Site. The results of previous pumping tests that have been described in documents already submitted to the MDEQ are summarized in this section.

Zone A Sands

Zone A sands are continuous along this section of the Menominee River and are present at depths of about 5 ft bls to 50 ft bls. Aquifer pumping tests were performed on four extraction wells screened into the Zone A sands, including Extraction Wells GMEW-1, GMEW-2, GMEW-5 and GMEW-6.

Extraction Well GMEW-1

In April 2001 a constant-rate pumping test was conducted on Extraction Well GMEW-1 at a rate of 25 gpm for approximately 45.5 hours. A detailed analysis of this test is provided in a report submitted to the MDEQ entitled, "*Phase 1 Pilot Study Report, Ford/Kingsford Site, Kingsford, Michigan*", dated January 2002. Extraction Well GMEW-1 is screened from a depth of 20 ft bls to 30 ft bls. Three phases of water level response were observed during the pumping test. The first phase was marked by a rapid depletion of storage, and the recharge boundary effects of the river (approximately 53 ft away) were almost immediately evident. During the second phase the slope of the drawdown increased indicating that the cone-of-depression from the pumped well intersected a discharge boundary. Water level drawdown stabilized during the third phase, which was attributed to the effects of recharge from the Menominee River becoming the dominant factor. Prior to encountering the discharge boundary, the transmissivity of the Zone A sands was determined to be approximately 1,250 feet squared per day (ft^2/day). Analysis of the late-time drawdown data, when the discharge boundary effects were evident, indicated that the transmissivity of the Zone A sands was approximately 568 ft^2/day. Based on the observed drawdown at the end of the pumping test, the specific capacity of Extraction Well GMEW-1 was determined to be approximately 2.6 gallons per minute per foot (gpm/ft).

Extraction Well GMEW-2

In October 2001 a constant-rate pumping test was conducted on Extraction Well GMEW-2 at a rate of 20 gpm for a period of 72.5 hours. The results of the pumping test were presented in a letter report to the MDEQ referenced as "*Phase IIA Pilot Study Results, Ford/Kingsford Site, Kingsford, Michigan*", dated July 2002. Extraction Well GMEW-2 is screened from a depth of 23 ft bls to 36 ft bls. The transmissivity determined from the drawdown and recovery data ranged from 1,915 ft^2/day to 3,745 ft^2/day, with at geometric average of 2,678 ft^2/day. The storage coefficients computed from analysis of the data ranged from 0.01 to 0.004, and the leakance coefficient ranged from 0.023 to 0.004 day^{-1}. Based on the observed drawdown at the end of the pumping test, the specific capacity of Extraction Well GMEW-2 was determined to be approximately 2.0 gpm/ft.

Extraction Well GMEW-5

In December 2002 a constant-rate pumping test was conducted on Extraction Well GMEW-5 at a rate of 10 gpm for a period of nine hours. The results of the pumping test were presented in a letter report to the MDEQ referenced as "*Phase IIA Pilot Study Results, Ford/Kingsford Site, Kingsford, Michigan*", dated July 2002. Extraction Well GMEW-5 is screened from a depth of 40 ft bls to 48 ft bls. Analysis of the drawdown data indicated a transmissivity of 4,679 ft^2/day. Analysis of the recovery data indicated a transmissivity of 2,005 ft^2/day. Based on the observed drawdown at the end of the pumping test, the specific capacity of Extraction Well GMEW-5 was determined to be approximately 2.0 gpm/ft.

Extraction Well GMEW-6

In July 2002 a constant-rate pumping test was performed on Extraction Well GMEW-6 at a rate of 10 gpm for approximately 2 days. The results of the pumping test were presented in a letter report to the MDEQ referenced as "*Phase IIA Pilot Study Results, Ford/Kingsford Site, Kingsford, Michigan*", dated

July 2002. Extraction Well GMEW-6 is screened from a depth of 39 ft bls to 46 ft bls. Analysis of the drawdown data indicated a transmissivity of 4,679 ft^2/day. Analysis of the recovery data indicated a transmissivity of 3,074 ft^2/day. Based on the observed drawdown at the end of the pumping test, the specific capacity of Extraction Well GMEW-6 was determined to be approximately 1.2 gpm/ft.

Zone B Sands

Zone B sands are discontinuous along this section of the Menominee River and, where present, are located at depths of about 95 ft bls to 120 ft bls. At some locations Zones B and C sands are in direct hydraulic connection with one another, and in fact could be considered either Zone B sands or the top of the Zone C sands. In general, the focus on the hydraulic testing of Zone B sands was on the sands screened by Monitoring Well GM-25B. Aquifer pumping tests were performed on two extraction wells screened into the Zone B sands, including Extraction Well GMEW-4 located 16 feet north of Monitoring Well GM-25B and Extraction Well GMEW-4R located 8 feet south of Monitoring Well GM-25B.

At the location of Extraction Wells GMEW-3 and GMEW-7, the Zone B sands and the top of the Zone C sands are in direct hydraulic communication with each other. This can be seen in Figure B-6, which is an east-west hydrogeologic cross section through Monitoring Well Nest GM-25 and Extraction Well GMEW-7. The results of the hydraulic testing of Extraction Well GMEW-3 is addressed in the Zone C sands section of this document, since Extraction Well GMEW-3 is screened proportionately more in the top of Zone C sands than in Zone B sands.

Extraction Well GMEW-4

In February 2002 a step pumping test was performed on Extraction Well GMEW-4 by pumping the well at 5 gpm, 10 gpm, and 15 gpm in 2-hour increments. Extraction Well GMEW-4 is screened from a depth of 100 ft bls to 120 ft bls. The results were presented in a letter report to the MDEQ referenced as "*Phase IIB Pilot Study Results, Ford/Kingsford Site, Kingsford, Michigan*", dated May 2004. Although an aquifer transmissivity was not calculated from the step pumping test data, the specific capacity of Extraction Well GMEW-4 at the end of the pumping period was determined to be 0.5 gpm/ft.

Extraction Well GMEW-4R

In December 2002 a step pumping test was performed on Extraction Well GMEW-4R by pumping the well at 5 gpm and 10 gpm in 2-hour increments. Extraction Well GMEW-4R is screened from a depth of 107 ft bls to 112 ft bls and from a depth of 117 ft bls to 127 ft bls. The results were presented in a letter report to the MDEQ referenced as "*Phase IIB Pilot Study Results, Ford/Kingsford Site, Kingsford, Michigan*", dated May 2004. Analysis of the drawdown data from the step pumping test on Extraction Well GMEW-4R indicated a transmissivity of 602 ft^2/day. Analysis of the recovery data indicated a transmissivity of 334 ft^2/day. Based on the observed drawdown at the end of the pumping test, the specific capacity of Extraction Well GMEW-4R was determined to be approximately 0.12 gpm/ft.

Zone C Sands

Zone C sands are continuous along this section of the Menominee River, except where truncated against bedrock highs at the locations of Soil Boring GMSB-118 and Monitoring Well GM-63B. Zone C sands are located at depths of about 100 ft bls to 180 ft bls. An aquifer pumping test had been performed on Extraction Well GMEW-3.

In November 2002, a constant-rate pumping test was conducted at a rate of about 25 gpm for a period of approximately four days on Extraction Well GMEW-3. Extraction Well GMEW-3 is screened from a depth of about 135 ft bls to 145 ft bls. The results were presented in a letter report to the MDEQ referenced as "*Phase IIB Pilot Study Results, Ford/Kingsford Site, Kingsford, Michigan*", dated May 2004. Analysis of the drawdown data from Extraction Well GMEW-3 indicated a transmissivity of 2,273 ft^2/day and a storage coefficient of 0.004. Analysis of the recovery data indicated a transmissivity of about 2,005 ft^2/day. Based on the observed drawdown at the end of the pumping test, the specific capacity of Extraction Well GMEW-3 was determined to be approximately 0.7 gpm/ft.

Pumping Test Analysis Fall 2003

Aquifer pumping tests were conducted on one existing and three new extraction wells screened in the Zone C sands between October 27, 2003 and December 6, 2003. The pumping tests were completed on Extraction Wells GMEW-3, GMEW-7, GMEW-8, and GMEW-9.

Pumping Test Procedures

Prior to, during, and after each of the pumping tests, groundwater elevation data was recorded in monitoring points to document groundwater elevation changes, if present. Monitoring point locations were selected to allow for representative groundwater elevation monitoring. Both newly installed and existing monitoring wells and piezometers were utilized as monitoring points during the pumping tests. Specific monitoring points used during each of the pumping tests are discussed in their respective sections and their locations are shown in Figure B-1.

All newly installed monitoring wells, piezometers, and extraction wells were surveyed with respect to a known geodetic datum point by STS Consultants of Marquette, Michigan, providing measuring point elevations (relative to mean sea level) and coordinates (relative to Michigan State Plane Coordinates). Groundwater level measurements were collected prior to, during, and after each phase of the pumping tests. Groundwater elevation measurements associated with the pumping tests were collected primarily with In-Situ data loggers. These downhole data loggers utilize pressure transducers to measure pressures associated with the water column height above the data logger and convert the pressure into a depth of water. Utilizing a location specific reference elevation, the data logger converted the depth of water to a groundwater potentiometric surface elevation. These data were recorded at a specified frequency programmed into the unit's onboard data logger. The data logger measurements were field verified using manual water level indicators at regular intervals during the pumping tests. The manually collected data provides a verification tool in the event that anomalies were observed in the automatically recorded data sets.

To establish groundwater elevation trends prior to and after each phase of the pumping tests, data loggers were placed in each monitoring well, piezometer, or extraction well associated with the selected observation network. The data recorders were programmed utilizing the manufacturer-supplied interface software to collect groundwater elevation data at appropriate time intervals determined for each portion of a specific pumping test (data loggers were programmed to collect measurements at intervals between 5 seconds to 1 minute). Each data logger associated with a specific pumping test was identified with a unique name that indicated the pumping test location, pumping test date and purpose. Upon completion of the specific pumping test (or portion of a test), the data was downloaded to a central file location and

backup files were created. Each data file contained the monitoring location, data logger identification number, pumping test name, pumping test duration, data collection frequency, user defined reference elevation, and data logger function data.

During the pumping tests, groundwater extraction was conducted utilizing a submersible Grundfos® pump, previously installed within the extraction well. The extraction well discharge was connected to an assembly that utilized a flow control valve and totalizing flow meter. Extraction flow rates were periodically verified during the pumping tests by diverting the discharge into a calibrated 250-gallon tank for a measured time period. Groundwater extracted during the pumping tests was pumped via a 2-inch diameter high-density polyethylene pipe to one of two 20,000-gallon tanks located next to the on-site groundwater pretreatment plant (approximately 1,000 to 2,000 feet from the pumping wells). The groundwater was then transferred from the tanks into the on-site groundwater pretreatment plant.

Pumping Test Analytical Methodology

Based upon the review of time-drawdown plots and the local hydrogeology, the Hantush-Jacob (1955) solution for a leaky confined aquifer was used to analyze the observation points (monitoring wells and piezometers) in each pumping test. Hantush and Jacob (1955) derived an analytical solution for predicting water-level changes in response to pumping in a leaky confined aquifer assuming steady flow (no storage) in the aquitard(s):

$$s = \frac{Q}{4\pi T}\int_{u}^{\infty}\frac{e^{-y-r^2/4B^2y}}{y}dy$$

$$u = \frac{r^2 S}{4Tt}$$

$$B = \sqrt{\frac{Tb'}{K'}}$$

where, s is the displacement [L] in the observation well, Q is the pumping rate [L^3/T], T is the aquifer transmissivity [L^2/T], r is the radial distance [L], S is the coefficient of storage in the aquifer [dimensionless], t is the time since pumping began [T], B is the leakage factor [L^{-1}], b' is the thickness of the aquitard overlying the aquifer in the leaky system [L], and K' is the hydraulic conductivity of the aquitard overlying the aquifer in the leaky system [L/T].

The integral expression in the drawdown equation is commonly referred to as the *Hantush well function for leaky aquifers*, abbreviated as *w(u,r/B)*. The Hantush drawdown equation, therefore, can be written in compact notation as follows:

$$s = \frac{Q}{4\pi T}w(u, r/B)$$

ARCADIS utilized AQTESOLV for Windows (Duffield, 1999) to visualize the results of the Hantush-Jacob solution and to obtain the best fit for the groundwater elevation data collected by the data loggers. AQTESOLV for Windows allows analysis of both constant- and variable-rate pumping tests using the Hantush-Jacob solution. Hantush (1961a,b) also derived equations for the effects of partial penetration in a leaky aquifer.

The assumptions for the Hantush-Jacob (1955) solution are as follows:

- aquifer has infinite areal extent
- aquifer is homogeneous, isotropic, and has uniform thickness
- aquifer potentiometric surface is initially horizontal
- aquifer is leaky
- flow is unsteady
- pumping well is fully or partially penetrating
- flow to pumping well is horizontal when pumping well is fully penetrating
- water is released instantaneously from storage with decline of hydraulic head
- diameter of pumping well is small so that storage in the well can be neglected
- confining bed(s) has infinite areal extent, uniform vertical hydraulic conductivity and uniform thickness
- confining bed(s) is overlain or underlain by an infinite constant-head plane source
- flow in the aquitard(s) is vertical

The Hantush-Jacob solution was applied to observation points that were in the same interval as the extraction well being pumped, and were near the extraction well. Results from these observation points represent aquifer conditions in the vicinity of each pumping well.

Extraction Well GMEW-3

In October/November 2003 a constant-rate pumping test was conducted at a rate of about 25 gpm for a period of approximately 48 hours on Extraction Well GMEW-3. Although a pumping test had previously been performed on this well in 2002, cold weather conditions during the pumping test in 2002 had affected test performance. Therefore, a decision was made to rerun the pumping test, and to install Piezometer GMPZ-10 to further monitor the zone screened by Extraction Well GMEW-3. Extraction Well GMEW-3 is screened in the upper Zone C sands from a depth of 135 ft bls to 145 ft bls. The pumping test utilized Extraction Well GMEW-3 as the pumping well, and Extraction Well GMEW-7, Monitoring Wells GM-66B, GM-65 and GM-25B, and Piezometers GMPZ-4, GMPZ-7, and GMPZ-10 for groundwater elevation monitoring. Table B-1 summarizes the selected monitoring well network, well construction, and well locations relative to the pumping well. Figure B-6 shows the relationships of the screen setting for the monitoring points in the immediate vicinity of Extraction Well GMEW-3. Monitoring Well GM-66B, which is not shown on Figure B-6, was used as a background well to monitoring regional trends in groundwater levels for the Zone C sands.

Background monitoring was conducted at 1-minute intervals at each monitoring locations within the observation network. Background groundwater elevation data was collected beginning on October 27, 2003. Water level data collected from each of the monitoring points was corrected for regional trends, as detected in the background well (Monitoring Well GM-66B), prior to being used for the pumping test analysis.

The constant-rate pumping test on Extraction Well GMEW-3 was initiated on October 29, 2003 at 0930 and was terminated on October 31, 2003 at 1000. Groundwater recovery data was collected from all monitoring points for approximately 24 hours after pumping ceased.

Groundwater Level Response

The data collected during the pumping test on Extraction Well GMEW-3 shows that under pumping conditions a drawdown in water levels in the upper portion of Zone C sands was observed at Piezometers GMPZ-10 (1.16 feet) and GMPZ-4 (0.84 feet) located 18 and 50 feet away, respectively from Extraction Well GMEW-3. The data also shows that drawdown was observed in the lower portion of Zone C sands at Extraction Well GMEW-7 (0.20 feet) and Piezometer GMPZ-7 (0.18 feet), located 19 and 9 feet away, respectively from Extraction Well GMEW-3. Drawdown was also observed at Monitoring Well GM-65 (0.98 feet), which appears to be located in the overlying Zone B sands 10 feet away from Extraction Well GMEW-3. These data indicate that there is good hydraulic communication between these zones at this location.

Analysis of Hydraulic Properties

The data collected from Monitoring Well GM-65 and Piezometer GMPZ-10 were used to derive hydraulic parameters for the Zone C sands in the area around Extraction Well GMEW-3. Figure B-7 shows the data collected from Monitoring Well GM-65 with a best fit to the Hantush Jacob analytical solution using both the drawdown and the recovery data. The results indicate that the transmissivity of the Zone B and upper portion of the Zone C sands is 2,440 ft^2/day and the storage coefficient 0.005. Based on an r/B factor of 0.014 the leakance coefficient is calculated to be 4.9×10^{-3} day^{-1}.

Figure B-8 shows the data collected from Piezometer GMPZ-10 with a best fit to the Hantush Jacob analytical solution using both the drawdown and the recovery data. The results indicate that the transmissivity of the sands is 2,640 ft^2/day and the storage coefficient 0.003. Based on an r/B factor of 0.019 the leakance coefficient is calculated to be 2.9×10^{-3} day^{-1}. Based on the observed drawdown at the end of the test, the specific capacity of Extraction Well GMEW-3 was determined to be approximately 1.6 gpm/ft.

Extraction Well GMEW-7

In November 2003 a constant-rate pumping test was conducted at a rate of about 23 gpm for a period of approximately 48 hours on Extraction Well GMEW-7. Extraction Well GMEW- 7 is screened in the lower Zone C sands from a depth of 183 ft bls to 193 ft bls. The pumping test utilized Extraction Well GMEW-7 as the pumping well and Extraction Well GMEW-3, Monitoring Wells GM-65, GM-25B, GM-25C and GM-26B and Piezometers GMPZ-4, GMPZ-7, and GMPZ-10 for groundwater elevation monitoring. Monitoring Well GM-26B was used as a background well to monitoring regional trends in the groundwater level in the Zone C sands. Table B-2 summarizes the selected monitoring well network, screened intervals, and well locations relative to the pumping well.

Background monitoring was conducted at each monitoring location within the observation network. Background groundwater elevation data was collected on 1-minute intervals at the monitoring locations beginning on November 17, 2003. The pumping test was initiated on November 21, 2003 at 0925 and was terminated on November 23, 2003 at 0930. Groundwater recovery data was collected from all monitoring points for approximately 24 hours after pumping ceased. Water level data collected from each of the monitoring points was corrected for regional trends, as detected in the background well (Monitoring Well GM-26B), prior to analysis.

Groundwater Level Response

The data collected during the pumping test on Extraction Well GMEW-7 shows that under pumping conditions a drawdown in water levels was observed in the lower portion of Zone C sands at Piezometer GMPZ-7 (2.52 feet), which is located 10 feet away from Extraction Well GMEW-7. In addition, drawdowns in water levels were also observed at the following monitoring points:

- In the upper portion of Zone C sands at Extraction Well GMEW-3 (0.54) and Piezometers GMPZ-4 (0.53 feet) and GMPZ-10 (0.55 feet), located 19, 57 and 19 feet away, respectively from Extraction Well GMEW-7.
- In Zone B sands at Monitoring Wells GM-25B (0.44 feet) and GM-65 (0.61) located 269 and 11 feet away, respectively from Extraction Well GMEW-7.
- In Zone D sands at Monitoring Well GM-25C (0.44 feet), located 267 feet away from Extraction Well GMEW-7.

These data indicate that there is good hydraulic communication between Zone B, C, and D sands in the area around Extraction Well GMEW-7. Refer to Figure B-6 for the relationship between screened intervals for these wells and piezometers.

Analysis of Hydraulic Properties

The data collected from Piezometer GMPZ-7 was determined to be the most applicable data to derive hydraulic parameters for the Zone C sands at this location. Figure B-9 shows the data collected from Piezometer GMPZ-7 with a best fit to the Hantush Jacob analytical solution using both the drawdown and the recovery data. The results indicate that the transmissivity of the sands is 1,770 ft^2/day and the storage coefficient 0.03. Based on an r/B factor of 0.01 the leakance coefficient is calculated to be 1.8×10^{-3} day^{-1}. Based on the observed drawdown at the end of the pumping test, the specific capacity of Extraction Well GMEW-7 was determined to be approximately 0.33 gpm/ft.

Extraction Well GMEW-8

A step pumping test was initiated on November 1, 2003 by pumping Extraction Well GMEW-8 in 2-hour increments at approximately 10 gpm, 20 gpm, 30 gpm, and 35 gpm. Data loggers were placed in the extraction well and nearby monitoring wells and piezometers to obtain data on groundwater responses to the pumping. The data collected during the step pumping test was used to establish a pumping rate for the constant-rate pumping test. Groundwater elevation data from the data loggers was collected at 5-second intervals from the extraction well and 15-second intervals from the monitoring wells and piezometers

throughout the testing period. The water level drawdown data collected from Extraction Well GMEW-8 during the step pumping test is shown in Figure B-10.

In November 2003 a constant-rate pumping test was conducted at a rate of about 25 gpm for a period of about 48 hours on Extraction Well GMEW-8. Extraction Well GMEW-8 is screened across the entire depth of Zone C sands at depths of 125 ft bls to 145 ft bls. The pumping test utilized Extraction Well GMEW-8 as the pumping well and Monitoring Wells GM-26B, GM-26C, GM-27B, GM-27C, GM-63B, and GM-66B along with Piezometer GMPZ-8 for groundwater elevation monitoring. Monitoring Well GM-66B was used as a background well to monitoring regional trends in groundwater levels in the Zone C sands. Table B-3 summarizes the selected monitoring well network, screened intervals, and well locations relative to the pumping well.

Background groundwater elevation data was collected at 1-minute intervals at the monitoring location beginning on November 2, 2003. The pumping test on Extraction Well GMEW-8 was initiated on November 4, 2003 at approximately 1115 hours. Groundwater recovery data was collected from all monitoring points for approximately 24 hours after pumping ceased. Water level data collected from each of the monitoring points was corrected for regional trends as detected in the background well (Monitoring Well GM-66B), prior to analysis.

Groundwater Level Response

The data collected during the pumping test shows that under pumping conditions drawdown in water levels, due to the pumping of GMEW-8, was observed in Piezometer GMPZ-8 (1.58 feet) and Monitoring Well GM-26C (0.58 feet) that are screened in Zone C sands located 10 and 295 feet away, respectively from Extraction Well GMEW-8. In addition, drawdowns in water levels were also observed at the following monitoring points:

- In Zone B sands at Monitoring Wells GM-26B (0.22 feet) and GM-63B (0.46), which are located 294 and 263 feet away, respectively from Extraction Well GMEW-8.

- In Zone D sands at Monitoring Well GM-27C (0.26), which is located 550 feet away from Extraction Well GMEW-8. Figure B-3 shows a bedrock high has been identified between Extraction Well GMEW-8 and Monitoring Well GM-27C, at the location of Monitoring Well Nest GM-63.

These data indicate that there is good hydraulic communication between Zone B, C, and D sands in the area around Extraction Well GMEW-8. Refer to Figures B-3 and B-4 for the relationship between screened intervals for these wells and piezometers.

Analysis of Hydraulic Properties

The data collected from Piezometer GMPZ-8 was determined to be the most applicable data to derive hydraulic parameters for the Zone C sands at this location. Figure B-11 shows the data collected from Piezometer GMPZ-8 with a best fit to the Hantush Jacob analytical solution using both the drawdown and the recovery data. The results indicate that the transmissivity of the Zone C sands is 1,560 ft^2/day and the storage coefficient 0.014. Based on an r/B factor of 0.041 the leakance coefficient is calculated to be 2.9 x 10^{-2} day^{-1}. Based on the observed drawdown at the end of the pumping test, the specific capacity of Extraction Well GMEW-8 was determined to be approximately 0.6 gpm/ft.

Extraction Well GMEW-9

In December 2003 a constant-rate pumping test was conducted at a rate of about 20 gpm for a period of about 30 hours on Extraction Well GMEW-9. Extraction Well GMEW-9 is screened in Zone C sands from a depth of 125 ft bls to 170 ft bls. The pumping test utilized Extraction Well GMEW-9 as the pumping well and Monitoring Wells GM-5, GM-25B, GM-25C, GM-26C, GM-66B along with Piezometers GMPZ-4, GMPZ-9 and GMPZ-10 for groundwater elevation monitoring. Monitoring Well GM-26C was used as a background well to monitoring regional trends in groundwater levels in the Zone C sands. Table B-4 summarizes the selected monitoring well network, screened intervals, and well locations relative to the pumping well.

Background monitoring was conducted at each monitoring locations within the observation network. Background groundwater elevation data was collected at 1-minute intervals at the monitoring locations beginning on December 1, 2003. Pumping was initiated on December 3, 2003 at approximately 1625 and was terminated on December 4, 2003 at 2234. Groundwater recovery data was collected from all monitoring points for approximately 24 hours after pumping ceased. Water level data collected from each of the monitoring points was corrected for regional trends as detected in the background well (Monitoring Well GM-26C), prior to analysis.

Groundwater Level Response

The data collected during the pumping test on Extraction Well GMEW-9 shows that under pumping conditions a drawdown in water levels in Zone C sands due to the pumping of GMEW-9 was observed in Piezometer GMPZ-9 (0.87 feet), and Monitoring Wells GM-5 (0.14 feet), GM-25C (0.15 feet) and GM-66B (0.12 feet), which are located 11, 447, 366, and 627 feet away, respectively from Extraction Well GMEW-9.

Analysis of Hydraulic Properties

The data collected from PiezometerGMPZ-9 was determined to be the most applicable data to derive hydraulic parameters for the Zone C sands in the area around Extraction Well GMEW-9. Figure shows the data collected from Piezometer GMPZ-9 with a best fit to the Hantush Jacob analytical solution using both the drawdown and the recovery data. The results indicate that the transmissivity of the sands is 3,102 ft^2/day and the storage coefficient 0.0005. Based on an r/B factor of 0.01 the leakance coefficient is calculated to be 2.8×10^{-3} day^{-1}. Based on the observed drawdown at the end of the pumping test, the specific capacity of Extraction Well GMEW-9 was determined to be approximately 0.9 gpm/ft.

10 Proposed Performance Monitoring Network for Zone B and C Extraction Wells under Updated Model Conditions

1. Introduction

This report is being submitted as an addendum to the report submitted to the Michigan Department of Environmental Quality (MDEQ) entitled "*Numerical Groundwater Flow Model"* ARCADIS, May 28, 2004. The May 2004 report documented a steady-state, three-dimensional groundwater flow model that was used to develop the basis for the design of a groundwater extraction and treatment system to capture groundwater adjacent to the Menominee River where groundwater constituent concentrations are above the generic acute groundwater surface water interface (GSI) criteria.

Subsequent to the submittal of the May 2004 report and receipt of MDEQ comments, ARCADIS has collected additional data from the installation and testing of groundwater extraction wells along the Menominee River, based on Scenario One (Section 5 of Numerical Groundwater Flow Model Report). The results of the additional characterization performed during the summer and fall of 2004 were incorporated into the original calibrated groundwater model. This addendum presents the results of additional groundwater flow simulations based on the updated model and presents a strategy for further model refinement based on the initial start-up and performance testing of the groundwater extraction system.

Section 2 summarizes the results of additional characterization, which is presented in the Performance Monitoring Plan, describes the revisions to the model and results of additional simulations, and discusses the proposed approach for refining the model based on performance monitoring.

1.1 Purpose and Scope

The original calibrated model was developed to be used as a tool to aid in designing and optimizing the performance of the groundwater extraction system once operation has begun. Additional performance monitoring data acquired during the initial operations, as described in the main body of this report, will be used to refine the model and improve the reliability of its performance. The updated model as a result of this future effort will be used to assist in the operation and optimization of the extraction system. Compliance will be demonstrated by measured hydraulic gradients toward the extraction well network from the Menominee River and by groundwater quality at the monitoring wells.

2. Revisions to the Model and Future Modeling Strategy

This section summarizes the revisions to the model as a result of the installation and testing of groundwater extraction wells along the Menominee River during the 2004 construction season, comments received from MDEQ in a letter dated September 24, 2004, and follow-up discussions with Rick Mandle of the MDEQ regarding the model in mid-December 2004.

The objective of this section is to present the results of a simulation requested by MDEQ that would be based on the most conservative estimates of hydraulic conductivity that are supported by the pumping tests to illustrate the conservative nature of the groundwater pumping estimates to achieve capture of the groundwater along the Menominee River. The conservative pumping simulation was completed after updating the model and assessing impact of the model changes on the calibration. The conservative pumping simulation increased the hydraulic conductivity of model layers 1 through 7 by a factor of 1.5. Under this scenario, the modeled transmissivity of the Zone A sands is treated as its maximum measured value near the river from aquifer pumping tests, while the Zone B and C sands are treated as 3 and 1.4 times greater than the measured maximum, respectively.

2.1 Comparison of Modeled and Measured Transmissivity in the Original Calibrated Model

The final hydraulic parameters for the calibrated model zonation for each layer were summarized in Table 2 and presented in plan view on Figures 10 through 17 in the Numerical Groundwater Flow Model Report [ARCADIS, 2004]. The conceptual stratigraphic column for the model is shown in Figure 1.

Horizontal hydraulic conductivity for the water bearing units (Zone A, Zone B, and Zone C sands) ranged between approximately 20 and 32 feet per day (ft/day) for fine sand to silty sand to approximately 160 ft/day for sand and gravel mixtures. In general, vertical anisotropy (e.g., ratio of horizontal to vertical hydraulic conductivity) within the sand units was varied between approximately 10 and 15 for less stratified morphologies and between 120 and 390 for interbedded morphologies.

The hydraulic conductivity values for the water bearing units (Zone A, Zone B, and Zone C sands) along the Menominee River are consistent with, or higher than, the results of pumping tests which are summarized in the Performance Monitoring Plan. The average modeled transmissivity of Zone A sands along the river was 3,120 ft^2/day (based on average hydraulic conductivity of 104 ft/day and thickness of 30 feet) is

consistent with the average transmissivity results from the Zone A sands pumping tests of 2,960 ft^2/day. The Zone B sands were modeled with an average transmissivity of 650 ft^2/day along the river, which is higher than the pumping test average of 170 ft^2/day. The Zone C sands were modeled with transmissivities ranging between 2,900 and 6,500 ft^2/day (based on hydraulic conductivity between 45 and 65 ft/day and saturated thickness between 60 and 100 feet), which is higher than the average transmissivity from the Zone C sands pumping tests of 2,300 ft^2/day.

The horizontal hydraulic conductivity of the aquitards ranged from 0.01 ft/day for interbedded silt and clay to approximately 5 ft/day for silt or sandy silt. The vertical anisotropy for the aquitards ranged from approximately 120 to 1200. The aquitard separating the Zone A sands from the Zone B sands (e.g., model layers 2 and 3) was modeled using hydraulic conductivities between 0.2 and 2 ft/day, resulting in a range of transmissivity between approximately 20 and 100 ft^2/day along the river. The deeper aquitard (e.g., layer 5) that separates the Zone B sands from the Zone C sands in certain areas along the Menominee River was modeled using conductivities between 0.2 and 35 ft/day, which translates to a range of transmissivity between 2 and 350 ft^2/day based on an average thickness of 10 feet.

Throughout the model layers, bedrock was treated using a single value for horizontal hydraulic conductivity (0.001 feet/day) and vertical hydraulic conductivity (0.0001 feet/day).

2.2 Additional Characterization & Specific Capacity Testing

Between June and November 2004, ARCADIS installed and tested 44 wells along the Menominee River. A detailed discussion of the well installation and testing is provided in the Performance Monitoring Plan.

2.2.1 Revised Stratigraphy

The additional soil boring logs were used to update the stratigraphy along the Menominee River as shown on Figure 2. The primary change in the stratigraphy as a result of the additional soil borings is related to the bedrock elevations in two primary areas. In the first area, between GMEWA-17 and GMEWA-21, the bedrock was encountered at approximately 920 ft MSL over a broader area than previously identified. At the second area between GMEWA-10 and GMEWA-12, bedrock was encountered at approximately 1,000 ft MSL to the base of the Zone A sands.

In general, the interpreted stratigraphy of the water bearing units (e.g., Zone A, Zone B, and Zone C sands) was consistent with prior interpretations and model conceptualization. However, the additional data lead to the refinement of the stratigraphy in two areas. The additional boring log data indicates that the thickness of the Zone A sands is slightly thicker between Extraction Wells GMEWA-14 and GMEWA-17 than other areas along the Menominee River. In addition, the lateral extent of the Zone B sands as depicted in the original model was too extensive near the river and is probably less distinct from the Zone C sands in this area. As a result of borings placed in the vicinity of Extraction Well GMEWC-6, the extent of the impacted mapable Zone B sands is relegated to the immediate area between and around Extraction Well GMEWC-6 and Monitoring Well GM-25 (A/B/C). A detailed discussion of the findings from the soil borings drilled in this area is provided in the Performance Monitoring Plan.

2.2.2 Specific Capacity Testing Results

Two areas showed specific capacity results above 10 gpm/ft. The first area between Extraction Wells GMEWA-14 and GMEWA-16 showed specific capacity results slightly above 10 gpm/ft. The second area was between Extraction Wells GMEWA-8 and GMEWA-11, which had values ranging from approximately 13 and 28 gpm/ft. The Zone A sands in both of these areas were thicker when compared to other locations with lower specific capacity (Figures 2 and 3).

Although several attempts were made to install extraction wells in the Zone B sands as discussed in the Performance Monitoring Plan, only Extraction Well GMEWB-1 was completed in this zone and its specific capacity is less than 0.1 gpm/ft.

Specific capacity tests were performed on 14 Zone C sands extraction wells. The results of these tests are shown on Figure 4 for Extraction Wells GMEWC-1 through GMEWC-8A along with transmissivity values from prior pumping tests performed on existing extraction wells, for comparison. As shown on Figure 4, Zone C sands specific capacity test results range from approximately 0.25 to 7.7 gpm/ft, with an average of about 1.3 gpm/ft. The Zone C sands locations with higher specific capacity generally exhibit a greater thickness of sand or gravel facies. The transmissivity estimates from pumping tests performed on existing wells along the Menominee River ranged from 1,560 ft^2/day (Extraction Well GMEW-8) to 3,100 ft^2/day (Extraction Well GMEW-9). Generally, the lower transmissivity values loosely correlate to specific capacity results on the order of 0.3 to 2.4 gpm/ft. A specific capacity estimate

of 4.7 gpm/ft was obtained from Extraction Well GMEWC-4 during the 4-hour pumping tests, which is closest to the maximum transmissivity value of 3,100 ft^2/day.

As a result of the lower specific capacity testing of Extraction Well GMEWC-6, two additional extraction wells (GMEWC-9 and GMEWC-10) were installed into the Zone C sands in the vicinity of Extraction Well GMEWC-6. It is anticipated that the combined pumpage from these wells will easily total the design pumping rate from Extraction Well GMEWC-6 for the Zone C sands, which is 20 gallons per minute (gpm).

2.3 Model Updates

The revisions in the updated calibrated groundwater model were primarily associated with refinement of the stratigraphy due to the broader and somewhat shallower bedrock highs between Extraction Wells GMEWA-10 and GMEWA-12 and Extraction Wells GMEWA-17 and GMEWA-21 (Figure 2). The extents of the sand zones and aquitard units were modified to accommodate the elevated bedrock zone in these areas. The same hydraulic conductivity values and anisotropy ratios were used as in the calibrated model. As there was limited additional information as to the eastern extents of the bedrock highs in these two areas, their extents were interpreted based on existing data. The bedrock high near Extraction Wells GMEWA-10 and GMEWA-12 was treated as a spire, with essentially the same dimensions east-west as north-south. The bedrock high near Extraction Wells GMEWA-17 and GMEWA-21 was interpreted to be approximately 2-times longer in the east-west dimension than the north-south. Ultimately, the additional data acquired through the installation of the performance monitoring network may aid in the interpretation of the bedrock geometry and improve the stratigraphic interpretations regarding the geometry of the sand zones.

Based on groundwater sampling performed during the installation and testing of the extraction wells, it appears that the north-south extent of groundwater constituent concentrations above the generic acute GSI criteria in the Zone A sands is slightly less extensive than thought when the calibrated model was developed. The groundwater extraction network was installed using the 70-foot line geometry as discussed under Scenario One (Section 5.1.1). The results from WET testing, if confirmed by analytical results (as discussed in the Performance Monitoring Plan) indicate that the four northernmost wells (GMEWA-26 through GMEWA-28A) and four southernmost wells (GMEWA-1 through GMEWA-4) are below acute GSI criteria. Assuming that these results will be confirmed, ARCADIS performed additional simulations assuming that these wells were not pumped. The remaining 21 Zone A sands wells (GMEWA-5

through GMEWA-25) were simulated with pumping rates of 10 gpm for a Zone A sands total of 210 gpm.

The conditions in the Zone B sands prevented successful completion of dedicated groundwater extraction wells in the impacted area that could be pumped at the design rate. In addition, the areal extent of the Zone B sands was limited to the immediate area around Monitoring Well GM-25 (A/B/C). For this reason, the only extraction well screened into the Zone B sands is Extraction Well GMEWC-6, which is screened in both the Zone B and C sands. Additional simulations were completed assuming that this well, when pumped (at 30 gpm) would produce 10 gpm from the Zone B sands.

The occurrence of the bedrock high between the southern Zone C sands Extraction Wells GMEWC-7 and GMEWC-8 dictated an increased spacing between these wells. Extraction Well GMEWC-8 is located midway between the northern and southern bedrock highs that have been discussed in the preceding section. The simulations that were performed to mimic the groundwater extraction system assumed a pumping rate of 20 gpm at each Zone C sands extraction well for a total of 160 gpm produced from the Zone C sands. As indicated above although all simulations for the Zone C sands assumed that Extraction Well GMEWC-6 would produce 20 gpm from the Zone C sands, it is envisioned that withdrawals (20 gpm) in the area of Extraction Well GMEWC-6 would result from combined pumpage from Extraction Wells GMEWC-6, GMEWC-9 and GMEWC-10.

2.4 Updated Model Calibration

The results of the updated model calibration statistics did not significantly change from the original model. The calculated RMS error for the updated model was 3.45, which is comparable to the calibrated model results of 3.41. The updated calculated mean error, -0.46 feet, is slightly higher than the calibrated value of -0.37. The updated mean average error was 2.33, which compares well with the calibrated value of 2.30 feet. These relatively small changes in the calibration statistics indicate that the model updates had a minor impact on the model.

Calculated calibration statistics changed significantly for the worse, in the case where the updated model hydraulic conductivities were increased by a factor of 1.5 for the conservative flow simulation. The calculated RMS error was 5.34, mean error was 3.42, and the mean average error was -2.42. These results indicate that the conservative pumping scenario simulation is a poorer match to site behavior than the

updated model; however, the intent of this simulation was to evaluate the impact of capture under conservative flow conditions, not to improve the match of the model.

2.5 Conservative Pumping Simulation Results

The conservative pumping simulation was performed using the updates to the model as discussed in Section 4.1 of the Performance Monitoring Plan. The simulated heads resulting from the non-pumping simulation (no extraction wells) with 1.5 times higher hydraulic conductivity were used to calculate drawdown under the revised pumping conditions:

- 21 - Zone A sands extraction wells (northern and southernmost 4 wells eliminated for this case based on water quality) pumping at 10 gpm each for a total of 210 gpm.

- 1 - Zone B sands extraction well at location of Extraction Well GMEWC-6, pumping at 10 gpm

- 8 – Zone C sands extraction wells pumping at 20 gpm each for a total of 160 gpm.

Capture analysis was performed using the methods in Section 5 of the Numerical Groundwater Flow Model Report [ARCADIS, 2004]. The extent and number of particles used in the capture analysis was modified consistent with the findings for the Zone A and Zone B sands water quality testing results from 2004. Figures 5 through 7 show the steady-state cone of depression (drawdown) and capture analysis results for the Zone A, Zone B, and Zone C sands, respectively. Note that the intent of these simulations is not necessarily to show that complete capture is achieved under these conservative conditions when the pumping rates are unchanged; rather the goal is to illustrate the areas where the model indicates potential for problems, so that the Performance Monitoring Plan can be tailored to collect the information necessary to optimize performance. The results of this simulation are intended to be used as a conservative bench-mark for evaluating the performance monitoring data; however, it is recognized that additional model refinement may be necessary as discussed in Section 4.0.

As shown in Figure 5, the simulated cone-of-depression in the Zone A sands is well developed across the entire line of extraction wells. The effect of superposition of pumping is more pronounced to the south, resulting in greater combined drawdown in this area. The results of the particle tracking analysis indicate that complete capture is

maintained in all but the four northernmost active extraction wells in the conservative pumping simulation. In the calibrated model, capture is maintained by these four extraction wells. As shown in Figure 5, the decreased capture efficiency is mainly shown between the Menominee River and the extraction wells at these northern wells; however, a few particles originating from upgradient areas would also flow past these extraction wells. This result suggests that the capture at the northern end of the Zone A sands extraction wells is most sensitive to estimates of hydraulic conductivity. Considering that this simulation treats the entire Zone A sands along the river equal to the maximum measured value of transmissivity, the results indicate that the overall estimate of pumping required is conservative.

Figure 6 illustrates the simulated cone of depression and capture in the Zone B sands resulting from the operation of Extraction Well GMEWC-6, which is screened in the Zone B and C sands, and due to pumping above and below in the Zone A and Zone C sands. Under these conditions, the model indicates that a well developed cone-of-depression would form around Extraction Well GMEWC-6, resulting in complete capture of groundwater in the area where the Zone B sands exists (around Monitoring Well GM-25A/B/C as shown on Figure 2). It is acknowledged that the model treatment of the Zone B sands is oversimplified, as the model treats the Zone B sands as continuous, a layer that in this area only extends a few hundred feet north and south of Extraction Well GMEWC-6. For this reason the flow estimate is conservative; however, it may be necessary to add Zone B sands extraction wells or increase pumping in the Zone C sands to achieve spatial coverage, since the unit is less well developed and less extensive than treated in the model. This issue will be addressed in future modeling and performance monitoring efforts.

As shown in Figure 7, the simulated combined influence of pumping in the Zone C sands creates cone-of-depression that covers the entire line of pumping wells. The cone-of-depression is best developed around the extraction wells north of the bedrock highs (Extraction Wells GMEWC-1 through GMEWC-7). The cone-of-depression surrounding Extraction Well GMEWC-8 is better developed to the south due to the influence of the bedrock high that truncates the Zone C sands. Based on the particle tracking results, it appears that the Zone C sands extraction well system would still achieve complete capture, particularly to the north. At Extraction Well GMEWC-8, a portion of the particle paths indicate flow beneath the river prior to capture. These results suggest that the capture performance at Extraction Well GMEWC-8 is sensitive to the model estimates of hydraulic conductivity. In addition, the influence of the geometry of the bedrock highs could also have an impact on capture performance. For this reason, the Performance Monitoring Plan will be developed to evaluate this area in

particular. However, the degree of capture demonstrated by the model under these conditions indicates that the overall estimate of flow is conservative, even for much higher transmissivity conditions than measured in the field.

2.6 Future Modeling Strategy

Based on the findings of the well installation activities during the 2004 construction season, it is recommended that additional model refinements efforts be completed after the installation of the proposed performance monitoring piezometers and monitoring wells. The data collected from the additional soil borings may enhance interpretation of the site stratigraphy and the monitoring wells and piezometers will provide a significant number of new points for model calibration.

The proposed performance monitoring network was developed using the updated model and conservative pumping scenario as a bench-mark to assess the sensitivity of capture performance to model assumptions. These results were combined with the revised stratigraphic interpretations resulting from the well installation and testing to gauge where the model performance is potentially less reliable or uncertain so that it could be addressed during the performance monitoring. For this reason, there are more monitoring points at the north end of the Zone A extraction well network and surrounding Zone C Extraction Well GMEWC-8, which is centered between the bedrock highs.

The locations of the proposed points are shown on Figure 8, using color-coded symbols for each zone. The Zone A sands points are shown in blue (36 locations), the Zone B sands points are shown in green (3 locations), and the Zone C sands points are shown in Red (38 locations). Figure 9 shows the Zone A sands monitoring points superimposed on the updated model drawdown to better illustrate the locations and coverage. Figure 10 shows the Zone B and Zone C sands monitoring points superimposed on the Zone C sands drawdown.

It is anticipated that the additional calibration points and systematic data collection strategy presented in the Performance Monitoring Plan will improve the reliability of the model to meet the ongoing objectives of the Consent Judgment. However, it is anticipated that the model will also be used as a tool to assist in the operation and optimization of the system. Future modeling work will be developed using the telescopic mesh refinement technique to reduce the size of the model and allow more refined treatment of the site stratigraphy.

3. Conclusions and Recommendations

3.1 Conclusions

The following conclusions were drawn from the results of the additional work:

- The calibrated model was updated to reflect the stratigraphic and hydraulic data collected during the installation and testing of the extraction well network that was based on Scenario One, from the Numerical Groundwater Flow Model Report [ARCADIS 2004]. The primary changes related to the extension of two bedrock highs and minor reconfiguration of the aquifer and aquitard hydraulic conductivity zonation. These changes did not significantly change the calibration statistics for the updated model. Additional model refinement should be completed after the performance monitoring network is installed, using the performance monitoring data collected during initial start-up to calibrate the model.

- The updated model was used to develop a conservative pumping scenario, where the hydraulic conductivity of layers 1 through 7 were multiplied by a factor of 1.5. The modeled transmissivity values were equal to the maximum measured in the Zone A sands, 3 times greater than the maximum measured in the Zone B sands, and 1.4 times greater for the Zone C sands. Pumping was simulated using a revised extraction well network based on the extent of groundwater exceedance of acute GSI criteria including: twenty-one Zone A sands extraction wells, one Zone B sands extraction well, and eight Zone C sands extraction wells, pumping at 10 gpm, 10 gpm, and 20 gpm, respectively, for a combined total of 380 gpm. The results indicated that a well developed cone-of-depression would result in the conservative pumping model, resulting in reduced capture efficiency only at the northern most end of the Zone A sands and less so near Extraction Well GMEWC-8 in Zone C sands. Ultimately, these results indicate that the overall estimate of pumping to achieve capture is conservative.

3.2 Recommendations

It is anticipated that the groundwater model will be utilized to assist in the evaluation of the performance of the groundwater extraction system.

Further refinement of the model should be completed after the installation of the performance monitoring network, using hydraulic data collected during the initial operation of the system. Synoptic groundwater elevation measurements will be

combined with datalogger measurements as individual wells are brought on-line and these data will also be used in future re-calibration of the model. The additional data will allow for a refined model that will prove useful in the operation and optimization of the extraction system.

May 1997

SUMMARY

Fish, arthropod, and mussel data were collected during 1996 to begin evaluation of how planned changes in river flow regulation from hydroelectric dams will affect the biota of the Menominee River in northeastern Wisconsin. Seven permanent study sites were established within riverine portions of the uppermost 51.5 miles of the Menominee River, and these were sampled using standardized techniques for fish, fish habitat, arthropods, and mussels. Four additional sites were sampled for arthropods on tributaries and a downstream area of the Menominee, and single reference sites on the St. Croix River and on the Chippewa River in northwestern Wisconsin were sampled for fish, fish habitat, and arthropods. For fish, 29 species were captured from the Menominee River sites (14-21 per site), 29 from the St. Croix, and 12 from the Chippewa. The St. Croix reference site (unregulated flows) had the highest species richness, diversity, and modified index of well being score (MIWB; an index of fish community quality) of all of the sites, whereas the Chippewa River reference site (highly regulated flows) had the lowest biomass, species richness, and diversity. Within the Menominee River, fish abundance, biomass, diversity, and MIWB scores were substantially higher in the lower portion of the study area than in the upper. Several fish species were common in the lower portion and absent in the upper. Some differences in habitat, primarily bottom substrate and cover, existed among sites, but these were unrelated to geographic patterns in fish community structure. Late September fish sampling gave different quantitative values for fish community structure than July/August sampling, but yielded similar qualitative patterns in community structure among sites. Growth rates of smallmouth bass at most Menominee River sites were below Wisconsin averages, but abundance of legal-sized fish was relatively high. For arthropods, 104 identifiable taxa (species or genera) were found at the combined Menominee River and tributary sites (26-46 per site), 69 were found at the St. Croix, and 14 were found at the Chippewa, which had very low arthropod abundance. The order Ephemeroptera had the most taxa at all sites, and the most individuals at all but two, where Chironomids (Diptera) were most numerous. No clear longitudinal patterns in arthropod taxa richness or abundance were evident within the Menominee River mainstem. Two adjacent sites in the lower portion of the study area had dramatic differences in taxa richness and abundance. For mussels, 14 species were collected in the Menominee River. Sites in the lower portion of the study area had higher species richness than sites in the upper portion. Nine species were restricted to the lower portion, but only one was restricted to the upper. Differences in fish and mussel communities between the upper and lower portions of the Menominee River study area could be due to natural barriers that restricted historical colonization of the upper portion, or alternatively could be due to recent extirpations from the upper portion.

INTRODUCTION

In 1995, the Wisconsin Department of Natural Resources (WDNR) began a research study to quantify the effects of hydroelectric power dams on biological communities in Wisconsin's larger rivers. This study focuses on riverine fish, aquatic arthropod, and mussel faunas, and has two phases:

I. Comparisons between river reaches with flows heavily regulated by dams and river reaches with few dams (1995-2000).

1. Intensive comparison between the heavily regulated Chippewa/Flambeau River system and the relatively unregulated St. Croix River system.
2. Extensive statewide comparison among river reaches for the development of an index of biotic integrity based on fish communities. This index will be used for the rapid bioassessment of human impacts, including flow regulation, on large river ecosystem health.

II. Evaluation of the changes in biota following a shift in flow regulation patterns in the Menominee River system (1996-2008).

The study emphasizes both the site-specific effects of flow regulation from individual dams and the system-wide cumulative effects of riverine habitat modification and fragmentation from multiple dams and impoundments. The rationale, goals, and design of the study are presented in detail in the formal research study proposal, available from John Lyons.

Phase II of the study, the subject of this report, has a before-and-after-control-impact (BACI) design (Underwood 1994), with intensive sampling of the biota of the Menominee River system scheduled for 1996-1998, before the planned shifts in flow regulation in 2001, and again in 2004-2006, after the biotic community has had a chance to adjust to the shifts in flows. Limited sampling will also occur during 1999-2003 to track the nature and rate of biological responses to flow changes. A site on the relatively unregulated St. Croix River and another site on the heavily regulated Chippewa River will be used as references ("control") for comparison with the Menominee River ("impact") sites.

This progress report summarizes results from the 1996 sampling in the Menominee River system, the first year of the "before" portion of Phase II. Much of the early part of the 1996 field season was spent in reconnaissance, identifying and delineating study sites. However, later in the year, fish, arthropods, and mussels were sampled, and these data are presented here.

STUDY AREA

The primary study area for phase II encompasses the upper portion of the Menominee River in northeastern Wisconsin, from Pemene Falls (River Mile (RM) 67.1) upstream 51.5 miles to the source of the Menominee at the confluence of the Michigamme and Brule rivers (RM 118.6) (Fig. 1). Within this stretch of river are five hydroelectric dams: Sturgeon Falls (RM 83.0), Little Quinnesec (Niagara)(RM 91.4), Big Quinnesec (RM 96.0), Kingsford (Henry Ford)(RM 101.5), and Twin Falls (RM 107.9) (Thuemler and Schnicke 1992). Just upstream of the start of the Menominee River are Michigamme Falls Dam, located on the Michigamme River at RM 0.2, and Brule Island Dam, located on the Brule River at RM 1.7. Flow through the Michigamme Falls Dam is heavily influenced by flows from three additional dams, Peavy, Hemlock, and Way, located further upstream in the Michigamme River system. Three waterfalls remain within the primary study area (several others were inundated by the hydroelectric dams): Pemene, Quivers (RM 72.9), and Sand Portage (Pier's Gorge)(RM 89.6).

The primary study area can be split into two subareas based on the planned shifts in flow regulation. The upper subarea extends from the Little Quinnesec Dam upstream to the Michigamme-Brule confluence (27.2 miles). This subarea is currently influenced by daily peaking operations at the Michigamme Falls, Twin Falls, Kingsford, and Big Quinnesec dams (Thuemler and Schnicke 1992). Peaking operations at all four dams are scheduled to change in 2001, when a new operating regime will be initiated. This regime mandates run-of-river flows during the spring, and for the rest of the year allows peaking operations only if the daily maximum flow does not exceed twice the daily minimum. The new regime should result in greatly reduced daily fluctuations in flow, and probably higher minimum flows as well. The lower subarea extends from Pemene Falls to the Little Quinnesec Dam (23.9 miles). This subarea is currently influenced by daily peaking operations at the Little Quinnesec Dam. The future operating regime of this dam has not yet been determined, but whatever the flow patterns, beginning in 2001, daily fluctuations in discharge from the Little Quinnesec Dam will be "re-regulated" at the Sturgeon Falls Dam to provide more stable flows downstream.

Based on initial reconnaissance in June 1996, a period of higher than normal flows, we established nine sampling sites in riverine segments within the primary study area. Each site contained one continuous mile of apparent riverine (i.e., non-impounded) habitat. Locations were chosen based on proximity to dams and waterfalls and ease of access. In the lower subarea, sites were established in two riverine reaches between Quivers and Pemene Falls (QF1 and QF2) and two below Sturgeon Falls Dam (SF1 and SF2). In the upper subarea, sites were located in two reaches below Kingsford Dam (KD1 and

KD2), one below Twin Falls Dam (TF1), and two below Michigamme Falls Dam (MF1 and MF2). Insufficient riverine habitat existed for a sampling site below the Big Quinnesec Dam, and we chose not to sample the riverine area below Little Quinnesec Dam because of uncertainty regarding future flow regulation patterns and concerns about the confounding impacts of historical point-source pollution problems. All nine sites were sampled for mussels during July or August 1996, four were sampled for arthropods (MF1, KD1, SF2, QF1), and six were sampled for fish and habitat (MF1, MF2, KD1, SF1, SF2, QF2). Additional reconnaissance and fish sampling in September 1996, a period of below-normal flows, clearly indicated that two sites, KD2 and MF2, were actually impounded and not comparable to the other sites. These two sites were then deleted from the sampling design, and data from them will not be reported here. Although they appear to be riverine, analyses of flow gage data indicate that sites TF1 and KD1 sometimes experience backwater effects from impoundments that are located just downstream of them (Tom Thuemler, WDNR, Peshtigo, personal communication). However, these two sites will be retained and will continue to be sampled in future years along with the remaining other five sites. The locations of the seven "final" primary sites are described more fully in Table 1. In 1997, an additional site may be added immediately below the confluence of the Michigamme and Brule rivers, just upstream from MF1.

Eight additional ("secondary") sites were sampled for arthropods in 1996 in the Menominee River system outside of the primary study area. Two were on the Menominee River below Pemene Falls, and six were on tributaries. Four of the eight sites, one on the Menominee and three on tributaries (Table 1), were judged suitable and will be resampled for arthropods in future years. An additional secondary site on the Pine-Popple River system may also be added.

Two reference sites were established, one on the relatively unregulated St. Croix River (MSC5), where daily peaking flows were absent, and the other on the Chippewa River below Cornell Dam (MC2), where major daily peaking occurred (Table 1). These sites were sampled for fish and arthropods in July or August 1996, but were not sampled for mussels. They will continue to be sampled for fish and arthropods in coming years, and will also be sampled for mussels if staff and funding are sufficient

METHODS

Fish

Fish were sampled throughout each study site during either July or August using two electrofishing techniques, a boat-mounted "mini-boom" shocker, and a pre-positioned bottom electrofishing grid. The mini-boom was used to capture medium- to large-bodied fishes. The mini-boom was a standard WDNR unit, with

a 3500 W AC generator that passed output through a transformer and pulsar unit to provide pulsed-DC current (60 Hertz, 25% duty cycle). Power output was kept between 7.5-10.5 A and 275-400 V. The anode was a single boom with a Wisconsin ring and 12-16 droppers, and the aluminum boat hull was the cathode. A single netter attempted to catch all fish observed that were large enough to be retained by a 3/4" stretch mesh dip net. The mini-boom was operated in a downstream direction over the entire length of each station (one mile). One shoreline and the middle of the channel were shocked during the daytime, and the remaining shoreline was shocked at night, for a total of three miles of mini-boom sampling. Preliminary studies in 1995 on the St. Croix, Chippewa, and Wisconsin rivers indicated that one mile of daytime shoreline mini-boom shocking gave a reasonably accurate and precise picture of fish community structure and composition, but that night shocking yielded great numbers and biomass and a wider size range of fish. The mid-channel shocking was included to capture fishes not closely associated with shoreline habitat.

Electrofishing grids (Bain et al. 1985) were used to capture small-bodied fishes in shallow shoreline habitats that could not be adequately sampled with the mini-boom. The grids were 6.6 X 26.3 ft, covering a rectangular bottom area of 173 ft^2. The long axes of the grid were made of steel wire and served as the electrodes; these wires were joined by ropes to form a rectangle. The electrodes were powered by a 3500 W generator that produced AC current at 7-11 A and 250-500 V. Girds were positioned on the bottom within 1 ft of shore in water less than 3.3 ft deep, with their long axis parallel to the shoreline. Grids were set and then left undisturbed for at least 15 minutes prior to activation. Bain et al. (1985) found this to be sufficient time for small fishes to recover from any disturbance caused by the setting of the grid. Power was then applied to grids for 30 seconds, and all stunned fish were collected with dip nets. In fast current, a small seine was positioned just downstream of the grid during sampling to catch drifting fish. Grids were set in pairs (each member of the pair separated by 10 m) at 13 randomly chosen locations over the entire length of each one mile site, for a total of 26 grid samples per site. Preliminary work in 1995 on the St. Croix and Wisconsin rivers indicated that 26 grid samples gave a reasonably accurate and precise estimate of the community structure and composition of small shoreline fishes.

In late September, the Menominee River study sites were resampled for fish using only the daytime shoreline miniboom sampling procedures. The goals of this sampling were to capture young-of-year fishes for an assessment of first-summer growth and to look at seasonal variation in fish community structure.

All captured fishes were identified to species, counted, and weighed in

aggregate. Gamefish (see Table 2) were measured for total length to the nearest mm. Scales were taken from a subsample of smallmouth bass and walleye for aging. Voucher specimens of difficult to identify or rare species were preserved for later examination in the laboratory, but most captured fish were returned to the river after processing.

The following summary statistics were calculated for each site (see Fausch et al. 1990 for formulae): total number of fish, total biomass, total species richness, species diversity (Shannon index) based on number and on biomass, evenness based on number and on biomass, and the number of individuals, biomass, and species richness of gamefish species and of riverine specialist species (require riverine habitat for entire life cycle; Kinsolving and Bain 1993)(Table 2). For the July and August sampling, data from both fish sampling methods were analyzed separately and aggregately by sampling site. We also calculated a modified index of well being from the daytime shoreline mini-boom data (Ohio EPA 1988). The MIWB combined information on fish abundance, biomass, and species diversity to produce an index of fish community quality. The MIWB values calculated here were not directly comparable to those from Ohio and other states because of differences in sampling procedures. For walleye and smallmouth bass with scale samples, ages and backcalculated lengths at each annulus were determined following procedures in Carlander (1982). Directly measured total lengths for young-of-the-year smallmouth bass and backcalculated lengths at older ages were compared among sites using analysis of variance (SAS 1990).

Fish Habitat

Data were collected from the grid locations on habitat parameters of importance to fish. The following variables were measured or visually estimated for each grid using standard procedures from Simonson et al. (1994): stream channel macrohabitat type (seven categories), shoreline vegetation/land use type (seven categories), cover types (four categories), cover densities (four levels), amounts of bottom substrates (seven types), depths (six positions), and current velocity (three positions). Mean values or percentage frequency of occurrence from all 26 grids were determined for each habitat variable for each site.

Arthropods

Arthropods, defined here to encompass aquatic insects, amphipods, and isopods, but not other taxa, were collected from each site by wading with a standardized combination of kick-net sampling and timed hand-picking of specific microhabitats (modified from Cuffney et al. 1993a). Microhabitat sampling was not done at the secondary sites. Kick-netting was conducted with

a long-handled D-frame net with number 30 mesh (600 µm). At each site a deep (> 3 ft) riffle/run location away from the shoreline and a shallow riffle/run location (< 2 ft) near the shoreline were sampled until a quart jar could be filled with material (mix of arthropods, plant material, detritus, etc.) from each location. If pools were present, an additional deep sample and shallow sample were collected. Samples of up to four microhabitat types -- rock, wood, silt/sand, and aquatic vegetation -- were then hand-picked for invertebrates for 5 minutes each. Not all microhabitats occurred at all sites.

Arthropod samples were preserved in alcohol and processed in the laboratory using standardized procedures (Cuffney et al. 1993b). For the microhabitat samples, all arthropods collected were identified to the lowest taxonomic level possible (usually genus or species) and counted. For the kick-net samples, a randomly chosen subsample of at least 150 organisms (or all that were present if less than 150 were collected) were identified and counted.

The two types of arthropod sampling will be used to assess different attributes of the overall arthropod community. Microhabitat samples will be used for quantitative comparisons of abundance and community composition and structure among sites. Kick-net samples will be used to calculate a variety of "biotic indices" to assess the quality and health of the community (Plafkin et al. 1989). However, many of these analyses are not yet complete, and only preliminary comparisons among sites for relative abundance, taxa (species and genera) richness, and community composition are presented here.

Mussels

Mussels were collected by hand from about five different locations within each site. Locations were chosen to represent the range of substrate and habitat conditions present in the site. At each location, all areas of the river channel were searched for mussels, and scuba was used in areas deeper than 2.5 ft. Generally, only living mussels were collected, but shells from dead mussels were also picked up if they were from species not yet encountered alive at the site. Bank areas were also surveyed for shells. Two to four people made collections for four to eight hours at each site. A "depletion curve" methodology was followed. Mussels were gathered in groups of 20, with care taken that all mussels, including small individuals embedded in the bottom, were collected from each portion of the bottom surveyed. Once a group of 20 mussels had been collected, each mussel was identified to species, counted, measured for total length and total height, and aged based on external shell characteristics. Excepting a few voucher specimens that were preserved, all specimens were carefully returned after processing to the area

where they had been collected. A cumulative species list was established based on all groups of mussels collected, and sampling continued until six consecutive groups of 20 failed to yield a "new" species of mussel not yet encountered at the site.

The depletion curve methodology yields good estimates of species presence-absence and relative abundance, but provides no data on density or biomass. We compared species richness and relative abundance among sites. The mussel sampling also yielded size and age distributions, but analyses of these data are not yet complete and are not included here.

RESULTS

Fish

For the combined miniboom and grid shocker data, a total of 29 fish species were captured from the five Menominee River sites (28 during July/August), and 33 were found at the Chippewa and St. Croix reference sites (Table 2). There were 21 species in common between the Menominee River and the reference sites. Fourteen to 21 species were encountered at individual Menominee sites, whereas 12 species were captured at the Chippewa site (MC2) and 29 at the St. Croix site (MSC5). No state threatened or endangered species were collected from the Menominee or Chippewa River sites, but three Wisconsin threatened species, river redhorse, greater redhorse, and gilt darter, were captured at the St. Croix reference site. Within the Menominee River, the number of fish, biomass, diversity based on biomass, and modified index of well being (MIWB) were higher in the three sites in the lower study subarea (QF2, SF2, SF1) than in the two stations in the upper subarea (KD1, MF1; Table 3). Species richness, diversity based on number, and evenness based on number and on biomass varied among sites with site MF1 having the lowest values for diversity and evenness. The St. Croix River reference site had a greater species richness, diversity based on number and on biomass, and MIWB than any of the Menominee River sites, and the Chippewa River reference site had a lesser biomass, species richness, and diversity based on number, but a higher evenness based on biomass than any of the Menominee River sites.

Different information about the fish community at each site was provided by the miniboom and grid shockers (Tables 4, 5). The grids tended to catch more fish than the miniboom, but grid-caught fish were usually small and miniboom-caught fish large, so the miniboom yielded nearly all of the biomass from each site. Although species richness values from the miniboom and the grids were similar, each gear type produced species not captured by the other gear type. The miniboom tended to have higher values for diversity and evenness based on number, but, despite an order of magnitude or more difference in total biomass

captured, the miniboom and grid had similar values for diversity and evenness based on biomass.

For gamefish species, variability occurred among sites, but with only limited geographic pattern (Table 3, 4, 5). The St. Croix River reference site had the highest number but the lowest biomass of gamefish, indicating that the St. Croix gamefish were on average much smaller than those at other sites. The fewest gamefish species were captured at the Chippewa River reference site.

Conversely, much stronger geographic patterns were evident for riverine specialist species (Table 3, 4, 5). The lower subarea of the Menominee had substantially higher numbers, biomass, and species richness of riverine specialists than the upper subarea. Four riverine specialist species, northern hog sucker, silver redhorse, golden redhorse, and blackside darter, were common in the lower subarea but absent in the upper (Table 2). The St. Croix River reference site had the highest species richness of riverine specialists (Table 3, 4, 5).

The time period of sampling on the Menominee River appeared to influence most measures of fish community structure (Table 6). Generally, daytime miniboom sampling in July/August yielded fewer individuals, species, and diversity based on number, but higher biomass, diversity based on biomass, and evenness based on biomass than late September sampling. Some exceptions to this pattern occurred at either site KD1 or MF1. Evenness based on number varied little between sampling periods, and the MIWB either did not differ (SF2, SF1) or was higher in late September (QF2, KD1, MF1).

Only the smallmouth bass was numerous enough at all five Menominee River sites to allow for a comparison of size structure and growth rates among sites (Table 2). During July/August 1996, smallmouth bass populations at all sites on the Menominee River except QF2 had relatively high proportions of legal-sized fish (12") compared to the two reference sites (Table 7). The reference sites had higher proportions of fish under 4". Growth rates of smallmouth bass in the Menominee River varied among sites (Table 8). Directly measured total lengths of young-of-the-year smallmouth bass in late September 1996 were greatest at site SF2 and least at KD1, but sample sizes at KD1 and MF1 were small and means for the five sites were not significantly different from each other. Conversely, backcalculated lengths from older smallmouth bass captured in July/August 1996 indicated that growth to age I, II, and III was fastest at KD1 and slowest at SF2, and that means for these two sites were significantly different.

Fish habitat

Habitat conditions were generally similar among sites, although certain cover and substrate characteristics varied (Table 9). All of the Menominee River and reference sites consisted exclusively or primarily of run habitat, but only the two reference sites had pool habitat. Bank vegetation for all sites was a mix of grass and forest with some shrubs. Water depths and velocities were similar among sites, although site MF1 had a relatively high current velocity. The dominant cover type was not consistent among sites, with either aquatic vegetation (i.e., macrophytes), large woody debris, boulders, or overhanging bank vegetation being most important, and no clear longitudinal pattern existed within the Menominee River. Cover density was highest at site MF1 and reference site MSC5 on the St. Croix River. Rocky substrate (sum of bedrock, boulder, rubble/cobble, and gravel substrates) dominated at sites SF2, MF1, and reference site MC2 on the Chippewa River, whereas fine substrate (sum of sand and silt substrate) dominated at the remaining sites.

Arthropods

Macro and microhabitats available for arthropods varied among sites. Pools did not occur at any of the Menominee River primary or secondary sites, but were present at both the St. Croix and Chippewa River reference sites (see Table 9). All four Menominee primary sites had rock and wood microhabitats, but only two had silt/sand and aquatic plants. The St. Croix and Chippewa sites each had rock, wood, and silt/sand microhabitats, but neither had aquatic plants.

A total of 1511 arthropod individuals and 104 identifiable genera or species were collected from the primary and secondary sites of the Menominee River, compared to 498 individuals and 69 genera or species from the St. Croix reference site, but only 22 individuals and 14 genera or species from the Chippewa reference site (Tables 10, 11, 12). A Wisconsin endangered species, the extra-striped dragonfly (*Ophiogomphus anomalus*) was collected from the Paint River secondary site at Crystal Falls, Michigan. This occurrence represents the first record of the species from Michigan (Bill Smith, WDNR, Madison, personal communication).

Differences were apparent in the relative abundance, species richness, and species composition of arthropods among sites (Table 10). Most sites were dominated by Ephemeroptera (mayflies) both in terms of numbers of individuals and numbers of taxa, but site MF1 of the Menominee River and the St. Croix River reference site (MSC5) had the most individuals in the order Diptera (predominantly Chironomidae (midges)). The Chippewa River reference site (MC2) had the lowest numbers of individuals and taxa of all the sites, despite

having the second highest sampling effort. No clear longitudinal patterns were apparent among the four primary Menominee River sites, nor between the primary and secondary sites of the Menominee River system. However, despite being only a few miles apart, with no major differences in flow pattern and no dams or major tributaries between them, the QF1 and SF2 sites on the Menominee were very different. The QF1 site had the second lowest taxa richness and lowest individual abundance within the Menominee River system, whereas the SF2 site the second highest taxa richness and individual abundance.

Mussels

Fourteen species and 1967 individuals (1947 alive, 20 dead) of freshwater mussels (family Unionidae) were collected from the seven sties within the primary study area of the Menominee River (Table 12). Three species of special concern in Wisconsin were collected: elktoe, creek heelsplitter, and round pigtoe. A clear longitudinal pattern in species distribution was evident. The four sites in the lower subarea (QF2, QF1, SF2, SF1) had substantially higher species richness than the three sites in the upper subarea (KD1, TF1, MF1). Although the number of individuals collected at each site is not a valid measure for comparison of abundances among site, the general impression of the field crew during sampling was that mussel density was much higher in the lower than in the upper subarea. Nine species were found only in the lower subarea, one was found only in the upper, and four were found in both. The dominant species found in the upper subarea were either cosmopolitan species found in a wide range of habitats (giant floater, fatmucket) or more characteristic of small streams (cylindrical papershell), whereas some of those from the lower subarea were characteristic of larger rivers (mucket, fluted-shell, black sandshell, round pigtoe) and others were habitat generalists (e.g., threeridge, giant floater, spike, fatmucket; Cummings and Mayer 1992).

DISCUSSION

Patterns within the Menominee

Longitudinal patterns in community structure and composition were evident for fish and mussels but not arthropods within the primary area of the Menominee River. For fish and mussels there were more individuals, greater biomass, and higher species diversity in the lower subarea than in the upper subarea. Modified index of well being scores indicated that fish community "quality" was much better in the lower subarea than in the upper. Conversely, for arthropods, there were greater differences in taxa richness and abundance between the two sites sampled in the lower subarea than between sites in the lower and upper subareas.

Most of the fish community differences between the two subareas were caused by disparities in the species richness, abundance, and biomass of riverine specialist species; riverine specialists such as northern hog sucker, silver redhorse, golden redhorse, and blackside darter were common in the lower subarea, but absent in the upper. Interestingly, the gamefish portion of the fish community differed little between the two subareas. The difference in mussel species richness between the two subareas was caused by the absence of several large river specialists and habitat generalists from the upper subarea.

The differences in fish and mussel communities between the upper and lower subareas could be due to natural factors. Sturgeon Falls was a historical barrier to upstream movement by lake sturgeon and perhaps other fishes migrating out of Green Bay (Thuemler and Schnicke 1992). It and other waterfalls may also have served as barriers to upstream movements of colonizing fish species as glaciers receded from what is now northern Wisconsin and the upper peninsula of Michigan, thus accounting for the current absence of certain species in the upper subarea. Freshwater mussel distribution and colonization opportunities are typically closely tied to those of fish because larval mussels must parasitize fish in order to complete their life cycle (Cummings and Mayer 1992). Many mussel species can only parasitize certain fish species. Further, fish are an important vector for upstream larval mussel movement; once the larvae drop off fish to settle into the substrate and metamorphose into adults, their ability to move upstream is greatly limited. In contrast, many aquatic arthropods have an aerial stage in their life cycle, and waterfalls are much less of a barrier to their colonization of upstream areas.

Unfortunately, data from prior to the 1970s on fish and mussels in the upper portion of the Menominee River are very limited, so historical distribution patterns must be inferred from current data. Judging from present fish distribution patterns (this study; Becker 1983; EA Science and Technology 1987; Thuemler and Schnicke 1992; Greg Seegert, EA Science and Technology, Deerfield, Illinois, personal communication), Sturgeon Falls may have been the historical upstream limit for northern brook lamprey, northern hog sucker, and perhaps green sunfish; Sand Portage Falls may have been the upstream limit for rosyface shiner and silver redhorse; and Little Quinnesec Falls may have been the upstream limit for golden redhorse, shorthead redhorse, and blackside darter. Based on recent mussel distribution patterns (this study; Mathiak 1979), the upstream limit for many species could be somewhere from Sturgeon Falls upstream to Little or Big Quinnesec Falls.

An alternative explanation for current fish and mussel distribution patterns is that at least some of the species now restricted to the lower subarea may have historically occurred in the upper subarea as well, but disappeared because of human impacts. Municipal and industrial pollution formerly caused fish kills downstream of the cities of Iron River (MI), Iron Mountain (MI), and Niagara (WI) (Thuemler and Schnicke 1992), and could have eliminated fish species such as rosyface shiner, northern hog sucker, silver and golden redhorse, and blackside darter and mussel species such as elktoe, spike, fluted-shell, and black sandshell that are sensitive to poor water quality (Starrett 1971; Trautman 1981). Dams and waterfalls would have prevented these species from recolonizing the upper subarea after water quality was improved in the 1970s and 1980s. Another possibility is that impoundment and flow regulation from dams contributed to the disappearance of riverine specialist fish and mussel species. By definition, riverine specialist fish species are absent from impoundments. Kinsolving and Bain (1993) found that riverine specialist fishes were particularly sensitive to short-term flow fluctuations and tended to avoid river areas influenced by daily hydropower peaking. Layzer et al. (1993) documented the significant decline in a mussel fauna below a hydropower peaking operation.

Fish habitat conditions were not closely related to fish community structure in the Menominee River, suggesting that factors other than habitat were of primary importance in determining fish community characteristics. For example, site SF2, which had predominantly rocky substrates, had a fish community very similar to site SF1, which had predominantly fine substrates. Site MF1 had the highest cover density, and thus some of the best fish habitat, and yet had the lowest biomass of fish.

Growth of smallmouth bass varied among the Menominee River sites, without any clear relation to habitat conditions or flow regulation patterns. Growth rates were near the statewide and northern Wisconsin averages at site KD1, but below average at the other sites (WDNR 1991). However, relative abundance of legal-sized fish was well above typical values for Wisconsin streams and rivers (Lyons and Kanehl 1993), suggesting that high smallmouth bass densities may have contributed to reduced growth.

Different values for fish community parameters resulted from sampling in July/August and sampling in late September. Thus, great care should be taken in making quantitative comparisons of fish data collected in different seasons. However, the general pattern of differences between the upper and lower subareas that was apparent from the July/August data was also clear in the late September data, indicating that the two time periods yielded

qualitatively similar results.

Comparisons with the reference sites

Although located in different parts of the state, the reference sites seem to be reasonably similar to the Menominee River sites in terms of fish and arthropod communities and fish habitat. There were many fish and arthropod species in common between the Menominee River and the St. Croix and Chippewa rivers. Some differences in fish and arthropod species composition were apparent between the St Croix River site and the other sites, but values for most measures of fish community structure were similar or overlapped. The gamefish faunas of the Menominee sites and the reference sites were especially similar. Fish habitat conditions also overlapped substantially among sites, although pool habitat was found only at the two reference sites. For fish, the Chippewa River site, which had heavily regulated flows, had a community most similar to that of the highly regulated upper subarea of the Menominee River, whereas the St. Croix River site, which had unregulated flows, had a community most similar to that of the lower subarea of the Menominee River, where flows were less heavily regulated than in the upper subarea. For arthropods, the St. Croix had the highest taxa richness, and the Chippewa the lowest, with the sites from the Menominee River system intermediate.

ACKNOWLEDGMENTS

The following people helped collect data on the Menominee River: Fish: Kent Niermeyer, Ed Avery, Tom Baumgartner, Matt Keefer, John Lyons, Kent Niermeyer, Jerry Peterson, Randy Piette; Arthropods: Dick Lillie; Mussels: Ron Benjamin, Collin Dovichin, Mark Endris, Bob Hay, Dave Heath, Lisie Kitchel, Jim Kreitlow, Bill Smith. Dave Michaud, Tom Theumler, and Dennis Geary provided information on potential sampling locations, access points, and hydropower dam operating regimes. Paul Kanehl and Matt Keefer aged the smallmouth bass scales. Matt Keefer sorted, and along with Bill Smith, helped identify arthropods. This study was funded by a gift from Wisconsin Electric Power Company to the Wisconsin Department of Natural Resources (activity code RSOE), and Federal Aid in Sport Fish Restoration, project F-85-P, study RSDK.

Table 1. Location of sampling sites. All primary sites are one mile in length; the location information refers to the downstream end of the site.

Code	River Mile	Location
Primary study area of Menominee River, WI/MI (fish, arthropods, mussels)		
QF2	68.3	4.6 miles below Quivers Falls and 1.2 miles above Pemene Falls, centered on Faithorn Landing (MI)
QF1	71.6	1.3 miles below Quivers Falls, 2.8 miles above Faithorn Landing (MI)
SF2	75.6	7.4 miles below Sturgeon Falls Dam, 2.7 miles above Quivers Falls, 1 mile below Saler Landing (WI)
SF1	81.6	1.4 miles below Sturgeon Falls Dam, 1.3 miles below Sturgeon Falls Dam Landing (MI)
KD1	99.9	1.6 miles below Kingsford Dam, 1.9 miles above Aurora Landing (WI)
TF1	106.7	1.2 miles below Twin Falls Dam, 2.4 miles above Kingsford Flowage Landing (MI)
MF1	116.8	1.8 miles below confluence of Michigamme and Brule rivers, 2.0 miles below Michigamme Falls Dam, and 1.6 miles above landing (WI)
Secondary study area of Menominee River system, WI/MI (arthropods only)		
CTHZ	65.9	Menominee River (WI/MI), at Marinette County (WI) County Highway Z bridge
PIKE	1.6	Pike River (WI), above Pike River road crossing
BRULE	7.9	Brule River (WI/MI), at WI Hwy 141
PAINT	13	Paint River (MI), at MI Hwy 69 near Crystal Falls

Table 1 continued on next page.

Table 1. Continued.

Code	River Mile	Location
Reference sites (fish, arthropods, and mussels(?))		
MC2	95.5	Chippewa River (WI), 2.3 miles below Cornell Dam, 2.8 miles above Willow Island Landing (Old Abe Lake)
MSC5	94.8	St. Croix River (WI/MN), 0.2 miles above Snake River mouth (MN), 0.3 miles above Soderbeck Landing (WI)

Table 2. Fish species captured during July/August (miniboom and grids combined) and in late September 1996 (in parentheses; daytime mini-boom from Menominee River only) from the study sites. An "R" after the scientific name indicates a riverine specialist species, a "G" indicates a gamefish species, and a "T" indicates a state of Wisconsin threatened species.

June 1998

SUMMARY

Fish, arthropod, and mussel data were collected during 1996 and 1997 to evaluate how planned changes in river flow regulation from hydroelectric dams will affect the biota of the Menominee River in northeastern Wisconsin. Eight permanent study sites were established within riverine portions of the uppermost 51.5 miles of the Menominee River, and these were sampled using standardized techniques for habitat, fish, arthropods, and mussels. Five additional sites were sampled for arthropods on tributaries and a downstream area of the Menominee, and single reference sites on the St. Croix River and on the Chippewa River in northwestern Wisconsin were sampled for habitat, fish, arthropods and mussels. Fish community structure and composition patterns were similar between 1996-1997. In 1997, 29 fish species were captured from the Menominee River sites (14-21 per site), 29 from the St. Croix, and 12 from the Chippewa. Within the Menominee River, fish abundance, biomass, diversity, and MIWB scores were higher in the lower portion of the study area. Several fish species were widespread and common in the lower portion but absent in the upper. Differences in habitat, primarily bottom substrate and cover, existed among sites, but these were unrelated to geographic patterns in fish community structure. Growth rates of smallmouth bass at most Menominee River sites were at or above northern Wisconsin averages, and abundance of legal-sized fish was relatively high. For aquatic insects, major differences in abundance and order-level community composition were observed among sites. The order Ephemeroptera (mayflies) or Diptera dominated at all sites, and the Chippewa River site had the lowest insect abundance, but no longitudinal patterns were evident within the Menominee River. Full identification of 1997 arthropod samples is not yet complete. For mussels, 14 species were collected in the Menominee River (2-12 per site), 18 were found in the St. Croix, and 2 were found in the Chippewa. The Chippewa site had very few live mussels, all of which were > 23 years old. Sites in the lower portion of the Menominee River study area had higher species richness than sites in the upper portion. Nine species were restricted to the lower portion, but only one was restricted to the upper. The absence of many fish and mussel species from the upper portion of the Menominee study area could be due to natural barriers that restricted historical colonization, or, alternatively, to recent extirpations.

INTRODUCTION

In 1995, the Wisconsin Department of Natural Resources (WDNR) began a research study to quantify the effects of hydroelectric power dams on biological communities in Wisconsin's larger rivers. This study focuses on riverine fish, aquatic arthropod, and mussel faunas, and has two phases:

I. Comparisons between river reaches with flows heavily regulated by dams and river reaches with few dams (1995-2000).

1. Intensive comparison between the heavily regulated Chippewa/Flambeau River system and the relatively unregulated St. Croix River system.
2. Extensive statewide comparison among river reaches for the development of an index of biotic integrity based on fish communities. This index will be used for the rapid bioassessment of human impacts, including flow regulation, on large river ecosystem health.

II. Evaluation of the changes in biota following a shift in flow regulation patterns in the Menominee River system (1996-2008).

The study emphasizes both the site-specific effects of flow regulation from individual dams and the system-wide cumulative effects of riverine habitat modification and fragmentation from multiple dams and impoundments. The rationale, goals, and design of the study are presented in detail in the formal research study proposal, available from John Lyons.

Phase II of the study, the subject of this report, has a before-and-after-control-impact (BACI) design (Underwood 1994), with intensive sampling of the biota of the Menominee River system scheduled for 1996-2000, before the planned shifts in flow regulation in 2001, and again in 2004-2006, after the biotic community has had a chance to adjust to the shifts in flows. A site on the relatively unregulated St. Croix River and another site on the heavily regulated Chippewa River will be used as references ("control") for comparison with the Menominee River ("impact") sites.

This progress report summarizes results from the 1997 sampling in the Menominee River system, the second year of the "before" portion of Phase II. 1997 data are also compared with results from the more limited 1996 sampling.

STUDY AREA

The primary study area for phase II encompasses the upper portion of the Menominee River in northeastern Wisconsin, from Pemene Falls (River Mile (RM)

67.1) upstream 51.5 miles to the source of the Menominee at the confluence of the Michigamme and Brule rivers (RM 118.6) (Figure 1). Within this stretch of river are five hydroelectric dams: Sturgeon Falls (RM 83.0), Little Quinnesec (Niagara)(RM 91.4), Big Quinnesec (RM 96.0), Kingsford (Henry Ford)(RM 101.5), and Twin Falls (RM 107.9) (Thuemler and Schnicke 1992). Just upstream of the start of the Menominee River are Michigamme Falls Dam, located on the Michigamme River at RM 0.2, and Brule Island Dam, located on the Brule River at RM 1.7. Flow through the Michigamme Falls Dam is heavily influenced by flows from three additional dams, Peavy, Hemlock, and Way, located further upstream in the Michigamme River system. Three waterfalls remain within the primary study area (several others were inundated by the hydroelectric dams): Pemene, Quivers (RM 72.9), and Sand Portage (Pier's Gorge)(RM 89.6).

The primary study area can be split into two subareas based on the planned shifts in flow regulation. The upper subarea extends from the Little Quinnesec Dam upstream to the Michigamme-Brule confluence (27.2 miles). This subarea is currently influenced by daily peaking operations at the Michigamme Falls, Twin Falls, Kingsford, and Big Quinnesec dams (Thuemler and Schnicke 1992). Peaking operations at all four dams are scheduled to change in 2001, when a new operating regime will be initiated. This regime mandates run-of-river flows during the spring, and for the rest of the year allows peaking operations only if the daily maximum flow does not exceed twice the daily minimum. The new regime should result in greatly reduced daily fluctuations in flow, and probably higher minimum flows as well. The lower subarea extends from Pemene Falls to the Little Quinnesec Dam (23.9 miles). This subarea is currently influenced by daily peaking operations at the Little Quinnesec Dam. The future operating regime of this dam has not yet been determined, but whatever the flow patterns, beginning in 2001 daily fluctuations in discharge from the Little Quinnesec Dam will be "re-regulated" at the Sturgeon Falls Dam to provide more stable flows downstream.

Based on reconnaissance in 1996, we established eight sampling sites in riverine segments within the primary study area (Table 1). At these sites data on habitat, fish, arthropods, and mussels were collected. Each site contained one continuous mile of riverine (i.e., non-impounded) habitat. Locations were chosen based on proximity to dams and waterfalls and ease of access. In the lower subarea, two sites were between Quivers and Pemene Falls (QF1 and QF2) and two are below Sturgeon Falls Dam (SF1 and SF2). In the upper subarea, one site was below Kingsford Dam (KD1), one was below Twin Falls Dam (TF1), and two were below Michigamme Falls Dam (MF0 and MF1). Insufficient riverine habitat existed for a sampling site below the Big Quinnesec Dam, and we chose not to sample the riverine area below Little

Quinnesec Dam because of uncertainty regarding future flow regulation patterns and concerns about the confounding impacts of historical point-source pollution problems. Although they appear to be riverine, analyses of flow gage data indicate that sites TF1 and KD1 experience backwater effects from impoundments that are located just downstream (Tom Thuemler, WDNR, Peshtigo, personal communication).

Five additional ("secondary") sampling sites were established for arthropods outside of the primary study area (Table 1, Figure 1). One (CTHZ) was on the Menominee River below Pemene Falls, and four (PIKE, BRULE, PINE, PAINT) were on tributaries.

Two reference sites were established, one on the relatively unregulated St. Croix River (MSC5), where daily peaking flows are absent, and the other on the Chippewa River below Cornell Dam (MC2), where major daily peaking occurs (Table 1, Figure 1). These sites were sampled for habitat, fish, arthropods, and mussels.

METHODS

Fish

Fish were sampled once per year throughout each study site between early June and Late August. Two electrofishing techniques were employed, a boat-mounted "mini-boom" shocker and a pre-positioned bottom electrofishing grid. The mini-boom, used to capture medium- to large-bodied fishes, was a standard WDNR unit, with a 3500 W AC generator that passed output through a transformer and pulsar unit to provide pulsed-DC current (60 Hertz, 25% duty cycle). Power output was kept between 7.5-10.5 A and 275-400 V for a total of about 3000 W. The anode was a single boom with a Wisconsin ring and 12-16 droppers, and the aluminum boat hull was the cathode. A single netter attempted to catch all fish observed that were large enough to be retained by a 19 mm stretch-mesh dip net. The mini-boom was operated in a downstream direction over the entire length of each station (one mile). One shoreline and the middle of the channel were shocked during the daytime, and the remaining shoreline was shocked at night, for a total of three miles of mini-boom sampling. Preliminary studies in 1995 on the St. Croix, Chippewa, and Wisconsin rivers indicated that one mile of daytime shoreline shocking gave a reasonably accurate and precise picture of fish community structure and composition, but that night shocking yielded great numbers and biomass and a wider size range of fish. The mid-channel shocking was included to capture fishes not closely associated with shoreline habitat.

Electrofishing grids (Bain et al. 1985) were used to capture small-bodied

fishes in shallow shoreline habitats that could not be adequately sampled with the mini-boom. The grids were 2 X 8 m, covering a rectangular bottom area of 16 m^2. The long axes of the grid were made of steel wire and served as the electrodes; the ends of these wires were joined by ropes to form a rectangle. The electrodes were powered by a 3500 W generator that produced AC current at 7-11 A and 250-500 V. Girds were positioned on the bottom within 0.3 m of shore in water less than 1 m deep, with their long axis parallel to the shoreline. Grids were set and then left undisturbed for at least 15 minutes prior to activation, which allowed sufficient time for small fishes to recover from any disturbance caused by the setting of the grid (Bain et al. 1985). Power was then applied to grids for 30 seconds, and all stunned fish were collected with dip nets. In fast current, a small seine was held just downstream of the grid during sampling to catch drifting fish. Grids were set in pairs (each member of the pair separated by 10 m) at 13 randomly chosen locations over the entire length of each one mile site, for a total of 26 grid samples per site. Preliminary work in 1995 on the St. Croix and Wisconsin rivers indicated that 26 grid samples gave a reasonably accurate and precise estimate of the community structure and composition of small shoreline fishes.

All captured fishes were identified to species, counted, and weighed in aggregate. Gamefish (Table 2) were measured for total length to the nearest mm. Scales were taken from a subsample of smallmouth bass for aging. Voucher specimens of difficult to identify or rare species were preserved for later examination in the laboratory, but most captured fish were returned to the river after processing.

The following summary statistics were calculated for each site (see Fausch et al. 1990 for formulae): total number of fish, total biomass, total species richness, species diversity (Shannon index) based on number and on biomass, evenness based on number and on biomass, and the number of individuals, biomass, and species richness of gamefish species and of riverine specialist species (require riverine habitat for entire life cycle, Kinsolving and Bain 1993; Table 2). Data from both fish sampling methods were analyzed separately and aggregately by sampling site. We also calculated a modified index of well being from the mini-boom data (Ohio EPA 1988). The MIWB combined information on fish abundance, biomass, and species diversity to produce an index of fish community quality. The MIWB values calculated here were not directly comparable to those from Ohio and other states because of differences in sampling effort. For smallmouth bass with scale samples, ages and backcalculated lengths at each annulus were determined following procedures in Carlander (1982).

Fish Habitat

The following variables were measured or visually estimated for each grid using standard procedures from Simonson et al. (1994): stream channel macrohabitat type (seven categories), shoreline vegetation/land use type (seven categories), cover types (four categories), cover densities (four levels), amounts of bottom substrates (seven types), depths (six positions), and current velocity (three positions). Mean values or percentage frequency of occurrence from all 26 grids were determined for each habitat variable for each site.

Arthropods

Arthropods were collected by three different methods -- kick nets, Hess samplers, and hand-picked microhabitats -- at one location within each site (modified from Cuffney et al. 1993a). Kick-netting was conducted with a long-handled D-frame net with 600 Ãm mesh. At each site a deep (0.75-1.25 m) riffle/run location away from the shoreline and a shallow riffle/run location (< 0.5 m) near the shoreline were sampled until a quart jar could be filled with material (mix of arthropods, plant material, detritus, etc.) from each location. At sites without deep habitats two shallow samples were taken. The Hess stovepipe sampler, equipped with 500 Ãm mesh neeting, provided a quantitative sample of 0.084 m^2 of the bottom. A single Hess sample was collected at each site, except SF2, where three were taken, and PIKE, PINE, and PAINT, where the sampler was not used. The sampler was placed on the bottom and then the top 5 cm of the substrate within the sampler was disturbed by hand to flush out arthropods. Any rocks within the sampler were examined and scraped to remove attached organisms. Four different microhabitat types -- rock, wood, silt/sand, and aquatic vegetation -- were sampled by hand-picking. Not all microhabitats occurred at all sites, and no microhabitats were sampled at PIKE and PINE. At each site sampled, a representative sample of each microhabitat was gathered until a shallow 30 X 40 cm tray had been filled. The sample was then hand-picked in the tray for three minutes using a modified random encounter approach that maximized the variety of invertebrates selected. In richly populated samples this approach only yielded a subsample of the organisms present.

Arthropod samples were preserved in alcohol and processed in the laboratory using standardized procedures (Cuffney et al. 1993b). For the Hess and microhabitat samples all arthropods collected were identified to the lowest taxonomic level possible (usually genus or species) and counted. For the kick-net samples, all specimens were identified to order and counted. Then a randomly chosen subsample of 150 organisms were identified to the lowest taxonomic level possible.

Arthropod data were compared among sites for density (Hess), relative abundance (kicknet, microhabitat), and community composition (all sampling methods). Because 1997 samples have not yet been completely processed, only preliminary comparisons are presented here.

Arthropod Habitat

Data were collected from one location within each site for water chemistry, qualitative water level and velocity, and bottom substrates. Velocity and substrate were assessed separately for deep and shallow areas. Substrate (10 categories) was visually estimated to the nearest 5% for the entire area within 10-20 m of the point where arthropods were collected. Conductivity and pH were measured with electronic meters that were calibrated daily; water temperature was measured with a hand thermometer.

Mussels

Mussels (family Unionidae) were collected by hand from about five different locations within each site. Locations were chosen to represent the range of substrate and habitat conditions present in the site. At each location, all areas of the river channel were searched for mussels, and scuba was used in areas deeper than 0.6 m. Generally, only living mussels were collected, but shells from dead mussels were also picked up if they were from species not yet encountered alive at the site. Bank areas were also surveyed for shells. Two to four people made collections for at least two hours at each site. A "depletion curve" methodology was followed. Mussels were gathered in groups of 20, with care taken that all mussels, including small individuals embedded in the bottom, were collected from each portion of the bottom surveyed. Once a group of 20 mussels had been collected, each mussel was identified to species, counted, measured for total length and total height, and aged based on external shell characteristics. Excepting a few voucher specimens that were preserved, all specimens were carefully returned after processing to the area where they had been collected. A cumulative species list was established based on all groups of mussels collected, and sampling continued until six consecutive groups of 20 failed to yield a "new" species of mussel not yet encountered at the site.

The depletion curve methodology yields good estimates of species presence-absence and proportional abundance for comparisons among sites, but provides no data on density or biomass. The mussel sampling also yielded size and age distributions, but analyses of these data are not yet complete and are not included here.

At three Menominee River sites (MF0, TF1, KD1) an additional shoreline mussel

"midden" search was carried out. At each site most of the length of both shorelines was viewed from a boat in an attempt to locate middens, concentrations of shells created by humans or other predators such as racoons. When middens were encountered, shells were identified to species and counted. As some shell middens can be greater than 100 years old, this sampling could provide insight into the mussel community in the river prior to hydroelectric dam construction.

RESULTS

Fish

In 1997 all eight Menominee River primary sites and both reference sites were sampled for fish. In 1996 only five Menominee sites (QF2, SF2, SF1, KD1, MF1) and the two reference sites had been sampled. For those sites sampled in both 1996 and 1997, summary statistics were generally similar between years (Table 2). Values for species richness, diversity based on number and on biomass, and evenness based on number and biomass showed little difference between years. Site MF1 on the Menominee and the Chippewa reference site yielded fewer individuals but higher biomass in 1997, whereas the St. Croix reference site had higher numbers and biomass in 1997. The remainder of this section will cover only 1997 results.

For the combined 1997 miniboom and grid shocker data, a total of 29 fish species were captured from the eight Menominee River sites (12-19 per site), 28 were found in the St. Croix reference site, and 14 were encountered at the Chippewa reference site (Table 3). The Menominee River and 18 species in common with the St. Croix site and 8 with the Chippewa site. No state threatened or endangered species were collected from the Menominee or Chippewa River sites, but two Wisconsin threatened species, river redhorse and greater redhorse, were captured in the St. Croix.

Within the Menominee River, the number of fish, biomass, diversity based on biomass, and modified index of well being (MIWB) were higher in the four sites in the lower study subarea (QF2, QF1, SF2, SF1) than in the four stations in the upper subarea (KD1, TF1, MF1, MF0) (Tables 4, 5). Species richness, diversity, and evenness varied among sites with site TF1 having the lowest values. The St. Croix reference site had the highest number of fish, species richness, diversity, and MIWB.

Different information about the fish community at each site was provided by the miniboom and grid shockers (Tables 5, 6). The grids tended to catch more fish than the miniboom, but grid-caught fish were usually small and miniboom-caught fish large, so the miniboom yielded nearly all of the biomass from each

site. Species richness, diversity, and evenness values from the miniboom and the grids were similar, but each gear type produced species not captured by the other.

For gamefish species, variability among sites had no obvious geographic pattern (Table 4, 5, 6). The St Croix reference site had the most individuals, site TF1 on the Menominee had the highest biomass, and site MF1 had them most species. Most the St. Croix specimens were small young-of-year smallmouth bass, and biomass was realitvely low. The Chippewa reference site had the fewest individuals and species, but site QF1 on the Menominee had the lowest overall biomass.

Conversely, strong geographic patterns were evident for riverine specialist species (Table 4, 5, 6). The lower subarea of the Menominee had substantially higher numbers, biomass, and species richness of riverine specialists than the upper subarea. Four riverine specialist species, northern hog sucker, silver redhorse, golden redhorse, and blackside darter, were ubiquitous and common in the lower subarea but absent in the upper (Table 3). The St. Croix River reference site had the greatest number of individuals and highest species richness of riverine specialists (Table 4, 5, 6).

Only the smallmouth bass was numerous enough at all ten study study sites to allow for a comparison of size structure and growth rates among sites (Table 3). A wide size range of smallmouth bass was present at all sites, including legal-sized fish for sport harvest. Relative abundance of legal-sized individuals was highest in the four stations of the upper subarea of the Menominee. Growth rates of smallmouth bass varied relatively little among most sites, although TF1 had much slower growing age II and III fish than the other sites (Table 8).

Fish habitat

1997 habitat conditions in electroshocking grids were generally variable among sites, with little geographic pattern in values (Table 9). Pool habitat dominated the St. Croix reference site but was rare or absent in the other sites, where run habitat dominated. Bank vegetation for all sites was a mix of grass and forest, with some sites having shrubs. Nearshore water depths and velocities varied little among sites, although sites MF1 and MF0 had relatively high current velocities. The dominant cover type was not consistent among sites, with either aquatic vegetation (i.e., macrophytes), large woody debris, boulders, or overhanging bank vegetation being most important. No clear longitudinal pattern existed in cover type or density within the Menominee River. Similarly, there were no obvious longitudinal

patterns in substrates, with some sites dominated by rocky material, others by fines (sand and silt), and others by a near even mix of rocks and fines.

Arthropods

In 1997, aquatic arthropods were sampled at six (QF2, QF1, SF2, SF1, KD1, MF0) of the eight Menominee River primary sites, all five of the secondary sites, and both of the reference sites. In 1996, arthropods had been sampled at four of the primary sites (QF1, SF2, KD1, MF1), four of the secondary sites (CTHZ, PIKE, BRULE, PAINT), and both reference sites.

Locations sampled for arthropods generally had similar characteristics, with a few exceptions (Tables 10, 11). Values for pH and condicutivity varied only slightly among the Menominee primary and secondary sites and the St. Croix reference site, but were relatively low for the Chippewa reference site. Most locations had a mix of rocky and sand substrates, although the proportions of different rock types varied. Menominee site MF0 and the Chippewa reference had almost no sand or silt. Aquatic vegetation was absent from most locations, and where present was scarce and limited to shoreline areas.

Based on the quantitative Hess sampler, the insect orders Ephemeroptera (mayflies) and diptera (midges) dominated at most sites, although the relative proportion of each varied (Table 12). A substantial proportion of the order Coleoptera (beetles) occurred at Menominee primary site SF1 and secondary sites CTHZ and Brule. Densities varied varied greatly among sites from 210/m^2 at CTHZ (possible sample problems) to 870 at the Chippewa reference site to 3950 at Menominee primary site MF0. No clear longitudinal or geographic trends were evident in either composition by order or density.

The orders Ephemeroptera and Plecoptera were also dominant in composite kick-net sampling, with Coleoptera as the third most abundant order at most sites (Table 13). The Chippewa reference site had the fewest individuals collected. Again, no clear longitudinal or geographic trends were evident among sites, nor were there consistent distribution patterns between shoreline and deep across sites.

Although the general overall pattern was similar between Hess and composite samples, for individual sites the two methods sometimes gave very different pictures of the insect community. For example, at Menominee primary site KD1, Hess sampling indicated that Diptera was dominant (83%) and Ephemeroptera relatively unimportant (6%). But in composite sampling Ephemeroptera was dominant (57-63%) and Diptera was secondary in importance (11-20%).

For microhabitat sampling, only rocks were present at all sites, although wood was lacking from only Menominee primary site SF1 and the Chippewa reference site (Table 14). For rock microhabitats, relative abundances were generally similar among sites, although the Chippewa reference site again had the lowest number. Ephemeroptera was the most common order at most sites, but excepting Menominee primary site QF2 and the Chippewa reference site, Diptera were relatively uncommon. Trichoptera (caddisflies) Plecoptera (stoneflies) were often numerous. For wood microhabitats, Ephemeroptera, Trichoptera, and Plecoptera were again the most numerous groups, with Diptera common at the St. Croix reference site.

Mussels

Mussel depletion sampling took place over two years, with seven of the Menominee sites sampled in 1996. The remaining Menominee site (MF0) and the St. Croix and Chippewa reference sites were sampled in 1997.

The number of mussel species varied substantially among rivers and sites (Table 16). The eight Menominee sites yielded a total of 14 species (2-12 per site), compared to two from the Chippewa reference site and 18 from the St. Croix. Of the 14 Menominee species, 12 were encountered in the St. Croix and one in the Chippewa. Three Wisconsin special concern species -- elktoe, creek heelsplitter, and round pigtoe -- were found in the Menominee and the St. Croix. One WI endangered species, the purple wartyback, was found in the Chippewa and St. Croix sites. The depletion methodology give only a qualitative idea of mussel abundance, but the Chippewa site clearly has a very low density mussel population. This site yielded only four live mussels, all of which were at least 23 years old.

Within the Menominee River, a clear difference was evident between the mussel faunas of the upper and lower subareas. The four sites in the lower subarea (QF2, QF1, SF2, SF1) had substantially higher species richness than the four in the upper subarea (KD1, TF1, MF1, MF0). The general impression of the field crew during sampling was that mussel density was higher in the lower than in the upper subarea. Nine species were found only in the lower subarea, one was found only in the upper, and four were found in both. The dominant species found in the upper subarea were either cosmopolitan species found in a wide range of habitats (giant floater, fatmucket) or more characteristic of small streams (cylindrical papershell), whereas some of those from the lower subarea were characteristic of larger rivers (mucket, fluted-shell, black sandshell, round pigtoe) and others were habitat generalists (e.g., threeridge, giant floater, spike, fatmucket; Cummings and Mayer 1992).

The midden search of three sites in the upper subarea yielded few old shells. No shells, new or old, were found on the shoreline of MF0. At TF1, 263 giant floater, 63 fatmucket, and 1 creek heelsplitter shells were found. One historic midden pile of 50 apparently very old fatmucket shells were found, but the remaining shells looked recently dead. The giant floater and fatmucket were found alive at this site in depletion sampling. The creek heelsplitter had not been found in depletion sampling, but given the freshness of the shell, probably occurs alive at the site in low numbers. At KD1, one elktoe, 95 giant floaters, and six fatmucket shells were found. No historic midden piles were found, and all shells appeared to be recently dead. The giant floater and fatmucket had been previously found at this site in depletion sampling, but the elktoe had not. Given the condition of the elktoe shell, the species probably occurs alive at the site in low numbers.

DISCUSSION

Patterns within the Menominee

In 1997, as in 1996, longitudinal patterns in community structure and composition were evident for fish and mussels but not arthropods within the primary area of the Menominee River. For fish and mussels there was higher species richness in the lower subarea than in the upper subarea. Fish biomass was also higher in the lower subarea. Complete data on arthropod taxa richness are not yet available, but no clear longitudinal trends were apparent in abundance or composition by order.

Most of the differences in the fish assemblages between the upper and lower subareas were caused by disparities in the species richness, abundance, and especially biomass of riverine specialist species; riverine specialists such as northern hog sucker, silver redhorse, golden redhorse, and blackside darter were common in the lower subarea, but absent in the upper. Interestingly, the gamefish portion of the fish community differed little between the two subareas. The difference in mussel species richness between the two subareas was caused by the absence of several large river specialists and habitat generalists from the upper subarea.

The differences in fish and mussel communities between the upper and lower subareas could be due to natural factors. Sturgeon Falls was a historical barrier to upstream movement by lake sturgeon and perhaps other fishes migrating out of Green Bay (Thuemler and Schnicke 1992). It and other waterfalls may also have served as barriers to upstream movements of colonizing fish species as glaciers receded from what is now northern Wisconsin and the upper peninsula of Michigan, thus accounting for the current absence of certain species in the upper subarea. Freshwater mussel

distribution and colonization opportunities are typically closely tied to those of fish because larval mussels must parasitize fish in order to complete their life cycle (Cummings and Mayer 1992). Many mussel species can only parasitize certain fish species. Further, fish are an important vector for upstream larval mussel movement; once the larvae drop off fish to settle into the substrate and metamorphose into adults, their ability to move upstream is greatly limited. In contrast, many aquatic arthropods have an aerial stage in their life cycle, and waterfalls are much less of a barrier to their colonization of upstream areas.

Unfortunately, data from prior to the 1970s on fish and mussels in the upper portion of the Menominee River are very limited, so historical distribution patterns must be inferred from current data. Judging from present fish distribution patterns (this study; Becker 1983; EA Science and Technology 1987; Thuemler and Schnicke 1992; Greg Seegert, EA Science and Technology, Deerfield, Illinois, personal communication), Sturgeon Falls may have been the historical upstream limit for northern brook lamprey, northern hog sucker, and perhaps green sunfish; Sand Portage Falls may have been the upstream limit for rosyface shiner and silver redhorse; and Little Quinnesec Falls may have been the upstream limit for golden redhorse, shorthead redhorse, and blackside darter. Based on recent mussel distribution patterns (this study; Mathiak 1979), the upstream limit for many species could be somewhere from Sturgeon Falls upstream to Little or Big Quinnesec Falls.

An alternative explanation for current fish and mussel distribution patterns is that at least some of the species now restricted to the lower subarea may have historically occurred in the upper subarea as well, but disappeared because of human impacts. Municipal and industrial pollution formerly caused fish kills downstream of the cities of Iron River (MI), Iron Mountain (MI), and Niagara (WI) (Thuemler and Schnicke 1992), and could have eliminated fish species such as rosyface shiner, northern hog sucker, silver and golden redhorse, and blackside darter and mussel species such as elktoe, spike, fluted-shell, and black sandshell that are sensitive to poor water quality (Starrett 1971; Trautman 1981). Dams and waterfalls would have prevented these species from recolonizing the upper subarea after water quality was improved in the 1970s and 1980s. Another possibility is that impoundment and flow regulation from dams contributed to the disappearance of riverine specialist fish and mussel species. By definition, riverine specialist fish species are absent from impoundments. Kinsolving and Bain (1993) found that riverine specialist fishes were particularly sensitive to short-term flow fluctuations and tended to avoid river areas influenced by daily hydropower peaking. Layzer et al. (1993) documented the significant decline in a mussel

fauna below a hydropower peaking operation.

Fish habitat conditions were not closely related to fish community structure in the Menominee River, suggesting that factors other than habitat were of primary importance in determining fish community characteristics. For example, site SF2, which had predominantly rocky substrates, had a fish community very similar to site SF1, which had predominantly fine substrates. Site MF1 had the highest cover density, and thus some of the best fish habitat, and yet had the lowest biomass of fish.

Growth of smallmouth bass varied relatively little among study sites, without any clear relation to habitat conditions or flow regulation patterns. Growth rates were at or above northern Wisconsin averages (WDNR 1991), and relative abundance of legal-sized fish in the upper subarea was well above typical values for Wisconsin streams and rivers (Lyons and Kanehl 1993). The slowest growth was observed at TF1, which had the most smallmouth bass individuals (excluding young-of-year), suggesting that high densities may have contributed to reduced growth.

Comparisons with the reference sites

Although located in different parts of the state, the reference sites seem to be reasonably similar to the Menominee River sites in terms of biotic communities and habitat. There were many fish, arthropod (based on 1996 data), and mussel species in common between the Menominee River and the St. Croix and Chippewa rivers. The St. Croix generally had the richest fauna for all three groups, but values for most measures of community structure overlapped. The gamefish faunas of the Menominee sites and the reference sites were especially similar. Habitat conditions also overlapped substantially among sites, although pool habitat was found only at the two reference sites. For fish and mussels, the Chippewa River site, which had heavily regulated flows, had a community most similar to that of the highly regulated upper subarea of the Menominee River, whereas the St. Croix River site, which had unregulated flows, had a community most similar to that of the lower subarea of the Menominee River, where flows were less heavily regulated than in the upper subarea. For arthropods (1996 data; Appendix 3, 4), the St. Croix had the highest taxa richness, and the Chippewa the lowest, with the sites from the Menominee River system intermediate.

ACKNOWLEDGMENTS

The following people collected and/or processed data from the study sites in 1996-97: Fish: Kent Niermeyer, Ed Avery, Tom Baumgartner, Connie Boehlke, Mary

Botzet, Matt Keefer, John Lyons, Kent Niermeyer, Jerry Peterson, Randy Piette, Jackie ??????; Arthropods: Dick Lillie, Connie Boehlke, Matt Keefer; Mussels: Ron Benjamin, Collin Dovichin, Mark Endris, Bob Hay, Dave Heath, Lisie Kitchel, Jim Kreitlow, Bill Smith. Dave Michaud, Tom Theumler, and Dennis Geary provided information on potential sampling locations, access points, and hydropower dam operating regimes. Paul Kanehl helped age the smallmouth bass scales. Bill Smith helped identify arthropods. This study was funded in part by a gift from Wisconsin Electric Power Company to the Wisconsin Department of Natural Resources (activity code SSIK), and Federal Aid in Sport Fish Restoration, project F-85-P, study SSDM.

. ɔle 14. Relative abundance and community composition of aquatic insect orders by microhabitat type during June 1997. Data represent number of samples of each microhabitat type (N), the mean number (X) and standard error (SE) of insects at each site by microhabitat type, and the relative percentage of the three dominant aquatic insect orders in each microhabitat, where E = Ephemeroptera, P = Plecoptera, T = Trichoptera, O = Odonata, M = Megaloptera, C = Coleoptera, D = Diptera, and H = Heteroptera (Hemiptera). Primary sites TF1 and MF1 were not sampled.

Table 15. Community composition (% of total individuals) represented by EPT (Ephemeroptera-Plecoptera-Trichoptera) taxa by collection technique during June 1997. Primary sites TF1 and MF1 were not sampled. [] indicates a pooled deep and shallow composite sample; "ns" equals "not sampled"; "sd" equals "sampled destroyed" owing to poor preservation; "none" indicates that the microhabitat was not present at the site.

Table 16. Freshwater mussels collected from the primary study sites on the Menominee River. The number of individuals combines both live and dead specimens (shells); over 99% were alive. A "SC" indicates a special concern and "E" and endangered species for Wisconsin; "L" = large river species, "M" = medium stream/small river species, "S" = small stream species, and "G" = habitat generalist (from Cummins and Mayer 1992).

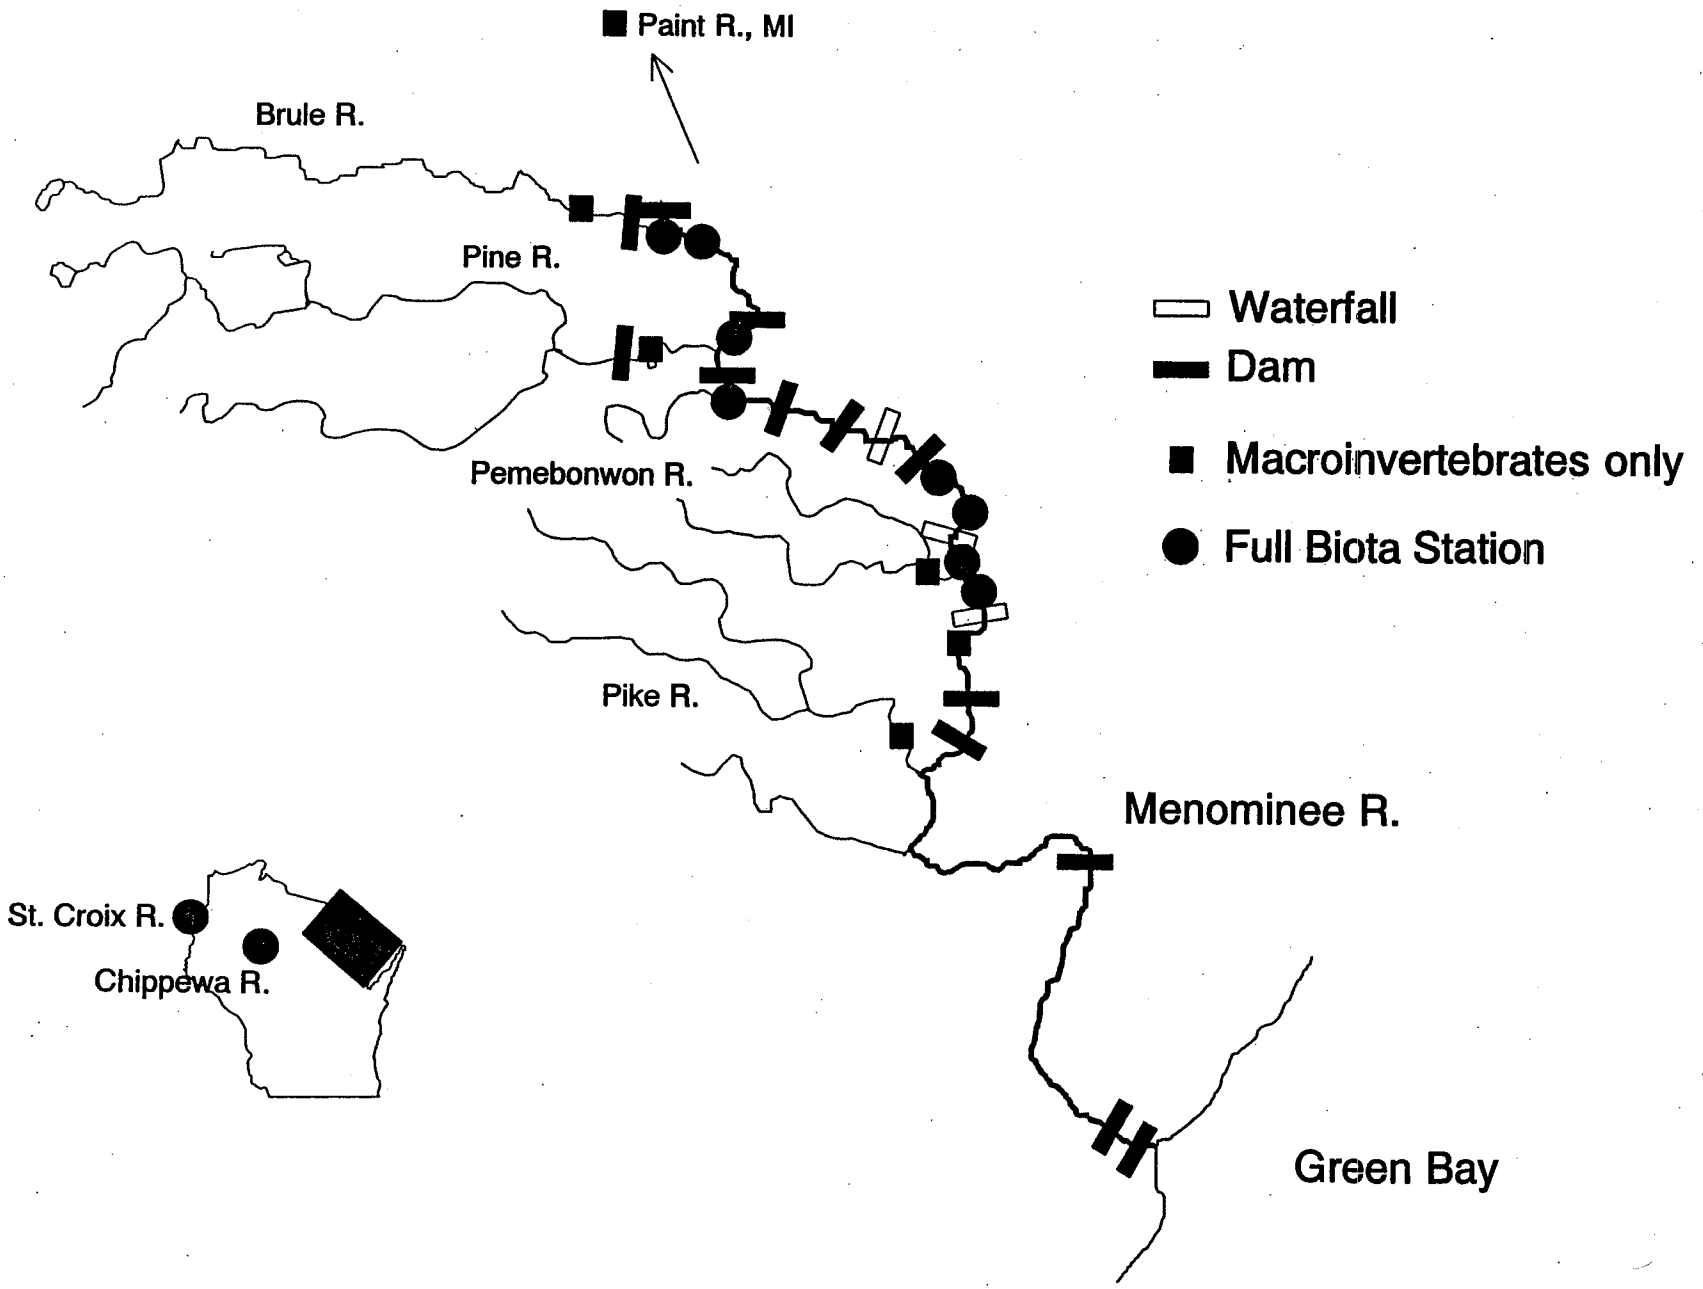
Figure 1. Map of Menominee River showing study sites, dams, and waterfalls. The inset map of Wisconsin shows the location of the St. Croix River and Chippewa River reference sites.

1996-97 Sampling



Appendix 1 - Scientific names of fishes and mussels mentioned in this report.

FISHES	
LAMPREY FAMILY	PETROMYZONTIDAE
Chestnut lamprey	*Ichthyomyzon castaneus*
Northern brook lamprey	*Ichthyomyzon fossor*
STURGEON FAMILY	ACIPENSIRIDAE
Lake sturgeon	*Acipenser fulvescens*
SALMON FAMILY	SALMONIDAE
Brown trout	*Salmo trutta*
Brook trout	*Salvelinus fontinalis*
MUDMINNOW FAMILY	UMBRIDAE
Central mudminnow	*Umbra limi*
PIKE FAMILY	ESOCIDAE
Northern pike	*Esox lucius*
Muskellunge	*Esox masquinongy*
MINNOW FAMILY	CYPRINIDAE
Spotfin shiner	*Cyprinella spiloptera*
Common carp	*Cyprinus carpio*
Brassy minnow	*Hybognathus hankinsoni*
Golden shiner	*Notemigonus crysoleucas*
Hornyhead chub	*Nocomis biguttatus*
Golden shiner	*Notemigonus crysoleucas*
Common shiner	*Luxilus cornutus*
Emerald shiner	*Notropis atherinoides*
Spottail shiner	*Notropis hudsonius*
Rosyface shiner	*Notropis rubellus*
Mimic shiner	*Notropis volucellus*
Northern redbelly dace	*Phoxinus eos*
Blacknose dace	*Rhinichthys atratulus*
Longnose dace	*Rhinichthys cataractae*
Creek chub	*Semotilus atromaculatus*

Appendix 1 continued on next page.

Appendix 1. Continued.

SUCKER FAMILY	CATOSTOMIDAE
Quillback	*Carpiodes cyprinus*
White sucker	*Catostomus commersoni*
Northern hog sucker	*Hypentelium nigricans*
Silver redhorse	*Moxostoma anisurum*
River redhorse	*Moxostoma carinatum*
Golden redhorse	*Moxostoma erythrurum*
Shorthead redhorse	*Moxostoma macrolepidotum*
Greater redhorse	*Moxostoma valenciennesi*
CATFISH FAMILY	ICTALURIDAE
Channel catfish	*Ictalurus punctatus*
Stonecat	*Noturus flavus*
Tadpole madtom	*Noturus gyrinus*
TROUTPERCH FAMILY	PERCOPSIDAE
Troutperch	*Percopsis omiscomaycus*
COD FAMILY	GADIDAE
Burbot	*Lota lota*
SUNFISH FAMILY	CENTRARCHIDAE
Rock bass	*Ambloplites rupestris*
Green sunfish	*Lepomis cyanellus*
Bluegill	*Lepomis macrochirus*
Smallmouth bass	*Micropterus dolomieu*
Largemouth Bass	*Micropterus salmoides*
Black crappie	*Pomoxis nigromaculatus*
PERCH FAMILY	PERCIDAE
Rainbow darter	*Etheostoma caeruleum*
Fantail darter	*Etheostoma flabellare*
Johnny darter	*Etheostoma nigrum*
Yellow perch	*Perca flavescens*
Logperch	*Percina caprodes*
Gilt darter	*Percina evides*

Appendix 1 continued on next page.

Appendix 1. Continued.

PERCH FAMILY	PERCIDAE (continued)
Blackside darter	*Percina maculata*
Slenderhead darter	*Percina phoxocephala*
Walleye	*Stizostedion vitreum*
DRUM FAMILY	SCIAENIDAE
Freshwater drum	*Aplodinotus grunniens*
SCULPIN FAMILY	COTTIDAE
Mottled sculpin	*Cottus bairdi*
MUSSELS	UNIONIDAE
Mucket	*Actinonaias ligamentina*
Elktoe	*Alasmidonta marginata*
Threeridge	*Amblema plicata*
Giant floater	*Anodonta grandis*
Cylindrical papershell	*Anodontoides ferussacianus*
Purple wartyback	*Cyclonaias tuberculata*
Spike	*Elliptio dilatata*
Wabash pigtoe	*Fusconaia flava*
Plain pocketbook	*Lampsilis cardium*
Creek heelsplitter	*Lasmigona compressa*
Fluted-shell	*Lasmigona costata*
Fatmucket	*Lampsilis siliquoidea*
Fragile papershell	*Leptodea fragilis*
Black sandshell	*Ligumia recta*
Hickorynut	*Obovaria olivaria*
Round pigtoe	*Pleurobema coccineum (=sintoxia)*
Pink heelspliter	*Potamilus alatus*
Pimpleback	*Quadrula pustulosa*
Squawfoot	*Strophitus undulatus*
Deertoe	*Truncilla truncata*

Appendix 2. Fish species captured during July/August 1996 (combined miniboom and grid sampling) and in late September 1996 (in parentheses; daytime mini-boom from Menominee River only) from the study sites. An "R" after the scientific name indicates a riverine specialist species, a "G" indicates a gamefish species, and a "T" indicates a state of Wisconsin threatened species.

Response of a riverine mussel community to a change in flow regulation

1999 Progress Report

Phase I: Menominee River

August 2000

Summary

Mussel and habitat data were collected during 1999 to evaluate how planned changes in river flow regulation from hydroelectric dams will affect the mussel biota in the Menominee River in northeastern Wisconsin. Currently, water levels during peaking operations fluctuate from 0.4 m to 1.1 m daily. Eight permanent study sites 80-100 m in length were established within riverine portions of the uppermost 36.4 km of the Menominee River. Study sites ranged in mean width from 26 m to 141 m. Maximum water depths at sites ranged from 0.5 to 5.3 m. Maximum water flows measured near the bottom ranged from 0.4 to 1.0 m/s and maximum mid-water column velocities ranged from 0.8 to 1.8 m/s. Snorkeling and SCUBA were used to collect quantitative mussel and habitat data at 1,714 quadrat locations along 80 transects (10 per site) using a stratified random sampling procedure. A total of 590 live individuals and seven species were captured. Giant Floater (*Anodonta grandis* form grandis) and fat mucket (*Lampsilis siliquoidea*) comprised 96 % of the mussels captured. Age of giant floaters ranged from 0-12 years and age of fat muckets ranged from 0-17 years. Growth rates were similar between giant floater and fat mucket with giant floater being slightly faster. The number of live mussels captured per site ranged from 0-315. Mussel density ranged from 0.0 to 10.0 per m^2 and was greatest in pool habitat. Mussel density was highest between 3 to 10 m from the ordinary high water mark (OHWM) along the bank. Suitable habitat for mussels decreased with increasing distance from the OHWM.

Introduction

Freshwater mussels are the most imperiled of all faunas globally, 73 % of the mussel fauna are considered extinct or imperiled (Master 1992). In the United States and Canada, nearly half of the 297 mussel species are considered threatened, endangered, or extinct and in Wisconsin, 19 of the 51 known species are listed as threatened or endangered (WDNR 1999).

River flow regulation for hydroelectric power generation has a major influence on freshwater mussel communities. Indeed, mussels may be among the aquatic animals most sensitive to artificial fluctuations in river flow. It is estimated that 30-60 % of the mussel fauna in rivers is destroyed by dams (Layzer et al. 1993; Williams et al. 1992). Causes may include dewatering, siltation, scouring, habitat alterations in general, or loss of fish hosts (Williams et al. 1993). As mussels play a key role in energy flow and habitat structuring in rivers, flow-induced changes in their communities may affect entire river ecosystems. However, few studies have documented flow-regulation impacts on mussels, particularly in north temperate rivers. More quantitative information on the relation between flow-regulation and mussel communities is urgently needed to help guide management decisions for many rivers, particularly during FERC relicensing of hydroelectric dams.

In 1999 the Wisconsin Department of Natural Resources (WDNR) began a research study to quantify the effects of hydroelectric power dams on the mussel communities in the Menominee River in northeast Wisconsin. This study is jointly funded by the WDNR and the Wisconsin Electric Power Company, owners of the hydroelectric dams in the study area. This mussel project compliments ongoing data collection for fish, macroinvertebrates, and habitat, and will provide an unprecedented large-scale study to test relations between river ecosystems and flow regulation. The recently signed "Wilderness Shores Agreement for the upper Menominee River system, Wisconsin and Michigan", provides a unique opportunity to better understand effects of flow regulation on mussels and to document how a return to more natural flow regimes may benefit mussel communities. Beginning in 2001, several hydroelectric dams in the system will substantially modify their operating regimes, leading to a fundamentally different and presumably more ecologically beneficial pattern of flow regulation. Quantification of the response of the mussel community to this change will provide unprecedented insight into the impacts of flow regulation on mussel communities and restoration strategies necessary to recover the biodiversity of multiple stream taxa, concurrently.

This study focuses on the riverine mussel fauna, and has two phases:

I. Pre-phase (1999 and 2000). Collect quantitative mussel population dynamics and habitat data on river reaches currently experiencing heavy peaking flows and quantify mussel habitat interactions.

II. Post-phase (after 2004). Collect quantitative mussel population dynamics and habitat data on river reaches after flow regulation changes occur. Compare pre-flow mussel population dynamics and habitat interactions with post-flow changes in mussel population dynamics and habitat interactions.

OBJECTIVES: Evaluate the response of the Menominee River mussel community to the changes in flow regulation that will occur as a result of the Wilderness Shores Agreement. Document changes in mussel species composition, density, biomass, and size and age structure associated with flow changes. Develop models that relate distribution and abundance of mussel species to in-river habitat variables that are influenced by flow regulation, such as water depth, velocity, and bottom substrate.

Study Area

The Menominee River in northeastern Wisconsin (Figure 1), from Big Quinnesec Dam (River km (RK) 154.5) upstream 36.4 km to the source of the Menominee River at the confluence of the Michigamme and Brule Rivers (RK 190.8) was selected as the study area. Four hydroelectric dams influence flows within the study area: Michigamme Falls Dam (RK 0.3) on the Michigamme River, Brule Island Dam (RK 2.7) on the Brule River, and Twin Falls Dam (RK 173.6) and the Kingsford Dam (RK 163.3) on the Menominee River (Thuemler and Schnicke 1992). Eight dams and two natural waterfalls prevent upstream fish migration below the study area. Eight sampling sites were located on the upper 36.4 km of the Menominee River in non-impounded riverine reaches only (Fig. 1). Two sites, MF1 (RK 190.0) and MF2 (RK 190.6) were located below the Michigamme Falls Dam and Brule River confluence. Four sites TF1 (RK 172.6), TF2 and TF3 (RK 172.9), and TF4 (RK 172.4) were located below the Twin Falls Dam. Sites TF2 and TF3 are adjacent channels separated by a long narrow island 80 m in length. Site TF2 is nearly completely dewatered at voluntary base flow levels (22.7cms) and completely dewatered at mandatory base flow levels (11.3 cms). The remaining two sites KD1 (RK 162.7) and KD2 (RK 161.9) were below the Kingsford Dam. All three dams presently have major daily peaking flows, but will go to much less dramatic daily flow fluctuations in 2001.

Currently, the upstream Michigamme Falls Dam may alter flows from 0 to 56.4 cms in a matter of hours, producing a change in river stage downstream as great as 1.1 m (WEPCO data for summer 1997). Flow through the Michigamme Falls Dam is heavily influenced by upstream flows from three additional dams, Peavy, Hemlock and Way. The Brule River enters about 0.3 km below the dam, and delivers 9.9-11.3 cms during summer low flows, somewhat dampening the flow extremes. Below the Brule confluence the Menominee River channel is wide and shallow, and despite the input from the Brule, large areas are dewatered during the low-flow phase of the peaking cycle (personal observations).

The Twin Falls Dam has peaking discharges that may fluctuate from 22.7 cms at voluntary base flows to 65.1 cms in the course of a day, creating a change in stage of up to 0.36 m downstream. About 0.16 km below the dam the river passes through a small island complex with several shallow side channels. During the low-flow phase of the peaking cycle these side channels have almost no flow and are partially dewatered.

The Kingsford Dam has flows that may vary from 25.5 to 85 cms during peaking operations, with a fluctuation in stage of up to 0.46 m downstream. The channel below the dam is fairly uniform in width and depth, and only relatively small areas along the channel margins are dewatered during the low flow phase of the peaking cycle.

Previously, the three Menominee River reaches were sampled semi-quantitatively for mussels in either 1996 or 1997. Mussel species composition and distribution were purported to be similar among the three river reaches (D. Heath, WDNR, pers. communication). Three (Michigamme Falls, Twin Falls) to six (Kingsford) species were present, and giant floater (*Adononta grandis*) and fatmucket (*Lampsilis siliquoidea*), both habitat generalists, dominated at all sites. In a statewide survey of mussels during 1973-1977, Mathiak (1979) found fat mucket and giant floater to be the most abundant mussels, and both were widely distributed across the state.

No reference sites (i.e., upstream unregulated sites) were found upstream of the study reaches. The Brule River reference site was dropped due to lack of mussels. Five additional sites on the Pike, lower Peshtigo, and lower Oconto Rivers were examined for use as a reference sites but also dropped, due to lack of similar species or recent changes in flow patterns below dams. A search for a suitable reference site will continue in 2000.

Methods

Mussel and habitat data were collected using a stratified random sampling procedure; strata were runs, riffle/rapids and pools. This design allowed extrapolation of mussel population parameters to the entire site and mapping of the distribution and abundance of individual mussel species in relation to habitat features and flow characteristics. Eight sites were quantitatively sampled on the Menominee River within the study area in 1999. A suitable reference site (i.e., a site located above all the hydroelectric dams) could not be located during the 1999 sampling season. Site locations were selected to represent available habitat within the river reach under normal mean daily flows. Sites were classified as pool, run, or riffle/rapids. Sample sites were 100 m in length, except sites TF2 and TF3, which were 80 m in length. Ten transects were sampled within each site. River width was measured at each transect location using a hand-held laser range finder. Transect lengths were one-half the river width or a maximum of 50 m in length starting at the ordinary high water mark (OHWM). Transect were randomly located from the downstream starting point of the site and randomly selected for left or right bank looking upstream. The transect line was a low stretch cord was marked every meter using a waterproof marker and a short piece of colored plastic ribbon. Transect lines were laid perpendicular to the main flow using a boat to drop a heavy anchor beyond the halfway point in the river, the transect line was then pulled tight and tied to a metal stake located at the OHWM. A 0.5 m square metal quadrat with an area of 0.25 m^2 was used to quantitatively sample mussels and habitat along each transect line (Strayer et al. 1995; Vaughn et al. 1995). Quadrats were located every meter for the first 10 m starting 1 m from the OHWM and every 2 m thereafter. Snorkeling and SCUBA gear were then used to collect quantitative mussel and habitat data (Miller et al. 1992; Miller and Nelson 1983; Isom and Gooch 1986).

From each quadrat data on habitat parameters of importance to mussels were collected. Total water depth (centimeters) and two velocity measurements (m/s) were recorded at each quadrat location. Depth was measured using an extendible staff gauge made from PVC pipe marked in 1 cm increments. Water velocities were measured at the substrate (within 2 cm) and at approximately 0.6 the total water depth (measured from the surface) using a hand-held flow meter (Global Water Flow Probe). A boat, positioned along the transect line, was used to measure mid-column water velocity at depths greater than 1.5 m. A SCUBA diver used a modified and water proofed hand-held flow meter to record bottom velocities in water greater than 1.8 m deep. Substrate (12 categories), macrophytes, and algae were recorded to the nearest 5 percent. Substrate embeddedness, the presence/absence of armored bottom, and upstream obstructions were also recorded.

Mussel data were collected after habitat data were recorded so that habitat would not be disturbed. The numbers of live, dead, embedded, and exposed mussels were recorded for each quadrat. Quadrats were visually observed and the number of embedded and exposed mussels recorded. Mussels were considered exposed if they were entirely out of the substrate and not in their normal upright position. All visible mussels and dead shells were then collected and placed in a mesh bag. The quadrat was then lightly fanned and large substrate excavated to expose any buried mussels, and then vigorously fanned to a depth of 10 cm to expose any deeply buried mussels. All captured mussels were taken to the boat and kept in water until processing. Mussels were identified to species using Stern (1990) and Cummings and Mayer (1992), individually measured for height and length, weighed, aged, and coded for shell wear before being returned to their original locations. Codes used to assess shell wear were: 0 = no wear, 1 = 0-25%, 2 = 25-50%, 3 = 50-75% and 4 = 75-100% of shell showing signs of wear.

Two-way analysis of variance will be used to compare mussel community and habitat data between the impact and reference sites before and after the change in flow regulation. Non linear models will be used to construct length at age curves. Univariate and multivariate statistical models will relate mussel abundance and distribution to habitat and flow characteristics.

Relationships between mussels and microhabitat variables will be examined using multivariate direct gradient analysis. Canonical correspondence analysis (CCA) is a direct gradient analysis that will be used to relate mussel species data to environmental data (ter Braak 1988) after the 2000 sampling season.

Initial Results

Mussels were sampled at eight sites on the upper Menominee River, two sites below Michigamme Falls Dam (MF1, MF2), four sites below Twin Falls Dam (TF1, TF2, TF3, TF4) and two sites below Kingsford Dam (KD1, KD2). Mussel sampling was conducted on 41 days from mid June to early October during 1999 (Table 1). Habitats sampled included runs, pools and riffle/rapids.

A total 1,717 quadrats were sampled along 80 transects at eight sites (Table 2). Seven species were captured during 1999 sampling; four species were habitat generalists, two species were indicative of small streams, one species was indicative of medium streams and small rivers. Two of the species are of special concern in Wisconsin (Table 3). A total of 590 live and 195 dead mussels were captured. Giant floater and fat mucket were the most frequently captured mussels at all sites. Total biomass of live mussels captured at all sites was 23.4 kg. Site TF4 had the highest number and biomass of mussels (315 live, 89 dead, 11,727 g live mussels) while site KD2 had the highest number of species (6 species)(Table 4). No live mussels were captured during sampling at site MF2, but live mussels were seen in the vicinity of the sampling area.

Mussel Density

Mussel density per square meter was calculated for each quadrat and assessed relative to the distance from the OHWM for pool and run/riffle habitats. Only one site, TF4, was considered as pool habitat, sites MF2 and TF2 were riffle/rapid habitat, and the remaining sites varied from moderate to fast run habitat depending on discharge. Mussels were not evenly distributed from the bank to the center of the channel nor were they evenly distributed between habitat types. Mussel density for site TF4 ranged from 1.0 to 10.0 per m^2 and was greater than sites with riffle or run habitat, which ranged from 0.0 to 2.0 per m^2 (Figure 2). Mussel density for site TF4 was highest 4 m from the OHWM and markedly reduced beyond 30 m from the OHWM. Mussel density in riffle and run habitat peaked at 5 m from the OHWM and was reduced beyond 10 m. No live mussels were found at site MF2 and only three giant floaters were found at site TF2. Both sites experience extensive de-watering at base flows. Across all sites, few mussels were found within 3 m of the OHWM for both pool and run habitat unless there was sufficient depth to prevent de-watering at base flows.

Age and Size Structure

Giant floater and fat mucket were the only mussel species abundant enough to plot age distribution, mean lenght, height, and weight. Giant floaters ranged in age from 0 to 12 years and fat muckets from 0 to 17 years old (Figure 3). The number of giant floaters beyond age 5 was sharply reduced indicating a change in recruitment or survival after 1994. As for the remaining species, elktoe mussels ranged from 4 to 12 years of age, Cylindrical papershell 2 to 9 years, wabash pigtoe 2 to 4 years, creek heelsplitter 2 to 8 years, and fluted-shell 9 to 16 years old.

Growth curves for giant floater and fat mucket (Figures 4, 5, and 6) showed the same overall nonlinear growth pattern, with giant floater having a slightly faster growth in height, length and weight than fat mucket. Fastest growth occurred in the first four years of life and declined thereafter.

Habitat

The site means for habitat variables grouped by distance from the OHWM are given in Table 5. Depth and velocity were directly influenced by discharge from the upstream dams at each site. Sampling was conducted when discharge was considered within normal mean daily flow for the time of year, but varied between sites. Mean river width ranged from 26 m (TF2) to 141 m (KD1). Site TF4 was the deepest site sampled and site TF2 the shallowest.

Suitable habitat for mussels decreased with increasing distance from the bank. The percent of fine substrates decreased as the distance from the OHWM and bottom velocities increased and were greatest in the first 10 m from the OHWM. Fine and large gravel were the dominant substrate type at intermediate and center portions of the river at all sites. Fine and coarse sand substrates suitable for mussels, were observed in the center portions of the channel beneath gravel substrate, indicating that sediment starved water released from the dams had scoured away the available fine substrates. The percent of quadrats with armored substrate increased substantially with distance from the OHWM, only three mussels were found in the 186 armored quadrats sampled.

Sites KD1 and MF1 had the greatest percentage of macrophytes; predominantly water celery (*Vallisneria americana*). Mussels were observed within the macrophyte beds. Site MF2 had the greatest percentage of algae covering the substrate.

Discussion

The distribution of mussels across the channel at each site was somewhat unusual. Mussels were concentrated at an intermediate distance from the banks, and were rare or absent from nearshore areas and also from the middle of the channel. In unregulated river reaches, mussels are usually common across the entire channel, whereas in reaches experiencing daily peaking they are often scarce along the margins of the channel but widespread throughout the intermediate and center zones. Lack of mussels at the edges is probably due to de-watering of some areas during the low-flow phase of the peaking cycle couple with dramatic fluctuations in velocity and depth in those nearshore areas that are not de-watered. The absence of mussels from the edges of the Menominee sites is thus not unexpected, but their absence from the center of the channel is. Absence in the center is more difficult to explain, and may be caused by particularly high velocities occurring at a critical time in the life stage of young mussels.

Suitable substrate for mussel colonization consisting of fine and coarse sands and loose fine gravel is limited in the center channel portions of the river. High velocities in the center of the channel have created an armored-like substrate and this substrate matrix may be impenetrable to mussels. Aggradation is universal below dams as fine substrates are scoured but the reservoir and dam proper block upstream sources. After flow changes occur in 2001, more stable flows should allow re-colonization of habitats currently being avoided by mussels where suitable substrate exists, but may not increase available habitat overall.

It is unlikely that any new species will enter the study area due to downstream dams preventing upstream movement of host fishes, but those species currently in the area should increase in number and biomass under more stable flows.

Acknowledgments

The following people helped to collect mussel data on the Menominee River: Corey Puzach and Shari Fanta. This study was funded in part by the Wisconsin Electric Power Company.

August 2000

Summary

Mussels (family Unionidae) and habitat data were collected during 1999 and 2000 to evaluate how planned changes in river flow regulation from hydroelectric dams will affect the mussel biota in the Menominee River in northeastern Wisconsin. Currently, water levels during peaking operations fluctuate from 0.4 m to 1.1 m daily. Eight permanent study sites 80-100 m in length were established within riverine portions of the uppermost 36.4 km of the Menominee River. Mean river width at study sites ranged from 26 m at TF2 to 141 m at KD1. Maximum water depths at sites ranged from 0.5 to 5.3 m. Maximum water flows measured near the bottom ranged from 0.4 to 1.0 m/s and maximum mid-water column velocities ranged from 0.8 to 1.8 m/s. Snorkeling and SCUBA were used to collect quantitative mussel and habitat data at 1,716 quadrat locations in 1999 and 1748 locations in 2000 along 160 transects (10 per site per year) using a stratified random sampling procedure. Mussel species richness and density was highly variable between sites. Mussel species richness increased with increasing distance downstream. Seven species and a total of 1,101 live individuals (590 in 1999 and 511 in 2000) were collected. All seven species observed were collected in each year but not all species were collected at all sites. *Pyganodon grandis* (Giant Floater) comprised 63 % of mussels collected and *Lampsilis siliquoidea* (fat mucket) comprised 33 % of the mussels collected. Age of *P. grandis* ranged from 0-12 years and age of *L. siliquoidea* ranged from 0-17 years. Survival rate for *P. grandis* averaged 63% and for *L. siliquoidea* was 79%. Growth rates were similar between *P. grandis* and *L. siliquoidea* with *P. grandis* being slightly faster. The number of live mussels collected per site ranged from 0-315. Mussel density ranged from 0.0 to 10.0 per m^2 and was greatest in run/pool habitat at site TF4. Mussel density was highest between 3 to 10 m from the ordinary high water mark (OHWM) along the bank and decreased with increasing distance form bank. Suitable habitat for mussels decreased with increasing distance from the OHWM.

Introduction

Freshwater mussels are the most imperiled of all faunas globally, 73 % of the mussel fauna are considered extinct or imperiled (Master 1992). In the United States and Canada, nearly half of the 297 mussel species are considered threatened, endangered, or extinct and in Wisconsin, 19 of the 51 known species are listed as threatened or endangered (WDNR 1999).

River flow regulation for hydroelectric power generation has a major influence on freshwater mussel communities. Indeed, mussels may be among the aquatic animals most sensitive to artificial fluctuations in river flow. It is estimated that 30-60 % of the mussel fauna in rivers is destroyed by dams (Layzer et al. 1993; Williams et al. 1992). Causes may include dewatering, siltation, scouring, habitat alterations in general, or loss of fish hosts (Williams et al. 1993). As mussels play a key role in energy flow and habitat structuring in rivers, flow-induced changes in their communities may affect entire river ecosystems. However, few studies have documented flow-regulation impacts on mussels, particularly in north temperate rivers. More quantitative information on the relation between flow-regulation and mussel communities is urgently needed to help guide management decisions for many rivers, particularly during FERC relicensing of hydroelectric dams.

In 1999 the Wisconsin Department of Natural Resources (WDNR) began a research study to quantify the effects of hydroelectric power dams on the mussel communities in the Menominee River in northeast Wisconsin. This study is jointly funded by the WDNR and the Wisconsin Electric Power Company, owners of the hydroelectric dams in the study area. This mussel project compliments ongoing data collection for fish, macroinvertebrates, and habitat, and will provide an unprecedented large-scale study to test relations between river ecosystems and flow regulation. The recently signed "Wilderness Shores Agreement for the upper Menominee River system, Wisconsin and Michigan", provides a unique opportunity to better understand effects of flow regulation on mussels and to document how a return to more natural flow regimes may benefit mussel communities. Beginning in 2001, several hydroelectric dams in the system will substantially modify their operating regimes, leading to a fundamentally different and presumably more ecologically beneficial pattern of flow regulation. Quantification of the response of the mussel community to this change will provide unprecedented insight into the impacts of flow regulation on mussel communities and restoration strategies necessary to recover the biodiversity of multiple stream taxa, concurrently.

This study focuses on the riverine mussel fauna, and has two phases:

I. Pre-phase (1999 and 2000). Collect quantitative mussel population dynamics and habitat data on river reaches currently experiencing heavy peaking flows and quantify mussel habitat interactions.

II. Post-phase (after 2004). Collect quantitative mussel population dynamics and habitat data on river reaches after flow regulation changes occur. Compare pre-flow mussel population dynamics and habitat interactions with post-flow changes in mussel population dynamics and habitat interactions.

OBJECTIVES: Evaluate the response of the Menominee River mussel community to the changes in flow regulation that will occur as a result of the Wilderness Shores Agreement. Document changes in mussel species composition, density, biomass, and size and age structure associated with flow changes. Develop models that relate distribution and abundance of mussel species to in-river habitat variables that are influenced by flow regulation, such as water depth, velocity, and bottom substrate.

Study Area

The Menominee River in northeastern Wisconsin (Figure 1), from Big Quinnesec Dam (River km (RK) 154.5) upstream 36.4 km to the source of the Menominee River at the confluence of the Michigamme and Brule Rivers (RK 190.8) was selected as the study area. Four hydroelectric dams influence flows within the study area: Michigamme Falls Dam (RK 0.3) on the Michigamme River, Brule Island Dam (RK 2.7) on the Brule River, Twin Falls Dam (RK 173.6) and the Kingsford Dam (RK 163.3) on the Menominee River (Thuemler and Schnicke 1992). Eight dams and two natural waterfalls prevent upstream fish migration below the study area. Eight sampling sites were located on the upper 36.4 km of the Menominee River in non-impounded riverine reaches only (Figure 1). Two sites, MF1 (RK 190.0) and MF2 (RK 190.6) were located below the Michigamme Falls Dam and Brule River confluence. Four sites TF1 (RK 172.6), TF2 and TF3 (RK 172.9), and TF4 (RK 172.4) were located below the Twin Falls Dam. Sites TF2 and TF3 are adjacent channels separated by a long narrow island 80 m in length. Site TF2 is nearly completely dewatered at voluntary base flow levels (22.7cms) and completely dewatered at mandatory base flow levels (11.3 cms). The remaining two sites KD1 (RK 162.7) and KD2 (RK 161.9) were below the Kingsford Dam. All three dams presently have major daily peaking flows, but will go to much less dramatic daily flow fluctuations scheduled to begin in 2001.

Currently, the upstream Michigamme Falls Dam may alter flows from 0 to 56.4 cms in a matter of hours, producing a change in river stage downstream as great as 1.1 m (WEPCO data for summer 1997). Flow through the Michigamme Falls Dam is heavily influenced by upstream flows from three additional dams, Peavy, Hemlock and Way. The Brule River enters about 0.3 km below the dam, and delivers 9.9-11.3 cms during summer low flows, somewhat dampening the flow extremes. Below the Brule confluence the Menominee River channel is wide and shallow, and despite the input from the Brule, large areas are dewatered during the low-flow phase of the peaking cycle (personal observations). The Twin Falls Dam has peaking discharges that may fluctuate from 22.7 cms at voluntary base flows to 65.1 cms in the course of a day, creating a change in stage of up to 0.36 m downstream. About 0.16 km below the dam the river passes through a small island complex with several shallow side channels. During the low-flow phase of the peaking cycle these side channels have almost no flow and are partially dewatered. The Kingsford Dam has flows that may vary from 25.5 to 85 cms during peaking operations, with a fluctuation in stage of up to 0.46 m downstream. The channel below the dam is fairly uniform in width and depth, and only relatively small areas along the channel margins are dewatered during the low flow phase of the peaking cycle.

Previously, the three Menominee River reaches were sampled semi-quantitatively for mussels in either 1996 or 1997 using a depletion curve methodology. Within the Menominee River, there was a clear difference between the upper and lower subareas separated by the Sturgeon Falls Dam. Mussel species richness was substantially higher at sites downstream of Sturgeon Falls compared to sites upstream. Mussel species composition and distribution were purported to be similar among the Michigamme, Twin Falls and Kingsford river reaches (WDNR 1997, unpublished). Three (Michigamme Falls, Twin Falls) to six (Kingsford) species were present, and *Pyganodon grandis* and *Lampsilis siliquoidea*, both habitat generalists, dominated at all sites. In a statewide survey of mussels during 1973-1977, Mathiak (1979) found *Pyganodon grandis* and *Lampsilis siliquoidea* to be the most abundant mussels, and both were widely distributed across the state.

No suitable reference sites (i.e., upstream unregulated sites) were found upstream of the study reaches. The Brule River reference site was dropped due to lack of mussels. Five additional sites on the Pike, lower Peshtigo, and lower Oconto Rivers were examined for use as a reference sites but also dropped, due to lack of similar species or recent changes in flow patterns below dams. No suitable reference site was located during 2000.

Methods

Mussel and habitat data were collected using a stratified random sampling procedure; strata were runs, riffle/rapids and pools. This design allowed extrapolation of mussel population parameters to the entire site and mapping of the distribution and abundance of individual mussel species in relation to habitat features and flow characteristics. Eight sites were quantitatively sampled on the Menominee River within the study area each year during in 1999 and 2000. A suitable reference site (i.e., a site located above all the hydroelectric dams or nearby river) could not be located. Site locations were selected to represent available habitat within the river reach under normal mean daily flows. Sites were classified as pool, run, or riffle/rapids. Sample sites were 100 m in length, except sites TF2 and TF3, which were 80 m in length and separated by a narrow island. Ten transects were sampled within each site each year. River width was measured at each transect location using a hand-held laser range finder. Transect lengths were one-half the river width or a maximum of 50 m in length starting at the ordinary high water mark (OHWM). Transect locations were randomly located from the downstream starting point of the site and randomly selected for left or right bank looking upstream. The transect line was a low stretch cord was marked every meter using a waterproof marker and a short piece of colored plastic ribbon. Transect lines were laid perpendicular to the main flow using a boat to drop a heavy anchor beyond the halfway point in the river, the transect line was then pulled tight and tied to a metal stake located at the OHWM. Additional weights were tied to the transect line if needed to keep the line near the bottom. A 0.5 m square metal quadrat with an area of 0.25 m^2 was used to quantitatively sample mussels and habitat along each transect line (Strayer et al. 1995; Vaughn et al. 1995). Quadrats were located every meter for the first 10 m starting 1 m from the OHWM and every 2 m thereafter. Snorkeling and SCUBA gear were then used to collect quantitative mussel and habitat data (Miller et al. 1992; Miller and Nelson 1983; Isom and Gooch 1986).

From each quadrat, data on habitat parameters of importance to mussels were collected. Total water depth (centimeters) and two velocity measurements (m/s) were recorded at each quadrat location. Depth was measured using an extendible staff gauge made from PVC pipe marked in 1 cm increments. Water velocities were measured at the substrate (within 2 cm) and at approximately 0.6 the total water depth (measured from the surface) using a hand-held flow meter (Global Water Flow Probe). A boat, positioned along the transect line, was used to measure mid-column water velocity at depths greater than 1.5 m. A SCUBA diver used a modified and water proofed hand-held flow meter to record bottom velocities in water greater than 1.8 m deep. Substrate (12 categories), macrophytes, and algae were recorded to the nearest 5 percent. Substrate embeddedness, the presence/absence of armored bottom, and upstream obstructions were also recorded.

Mussel data were collected after habitat data were recorded so that habitat would not be disturbed. The numbers of live, dead, embedded, and exposed mussels were recorded for each quadrat. Quadrats were visually observed and the number of embedded and exposed mussels recorded. Mussels were considered exposed if they were entirely out of the substrate and not in their normal upright position. All visible mussels and dead shells were then collected and placed in a mesh bag. The quadrat was then lightly fanned and large substrate excavated to expose any buried mussels, and then vigorously fanned to a depth of 10 cm to expose any deeply buried mussels. All collected mussels were taken to the boat and kept in water until processing. Mussels were identified to species using Stern (1990) and Cummings and Mayer (1992), individually measured for height and length, weighed, aged, and coded for shell wear before being returned to their original locations. Codes used to assess shell wear were: 0 = no wear, 1 = 0-25%, 2 = 25-50%, 3 = 50-75% and 4 = 75-100% of shell showing signs of wear.

A total of 18 habitat variables related to water depth, velocity, substrate type and cover were considered for inclusion into a habitat model relating the presence of live mussels. Analyses were conducted on 3,461 quadrat locations across all eight sites within the study area. Correlation coefficients (Pearson's >

0.60) were conducted on habitat variables to determine if any strong correlations existed between variables and if a single representative variable could be used. Logistic regression using stepwise analyses ($\alpha < 0.05$) was used to fit a model predicting the presence of live mussels to habitat variables. Two-way analysis of variance will be used to compare mussel community and habitat data between the impact sites before and after the change in flow regulation.

Results

Mussels were sampled at eight sites on the upper Menominee River, two sites below Michigamme Falls Dam (MF1, MF2), four sites below Twin Falls Dam (TF1, TF2, TF3, TF4) and two sites below Kingsford Dam (KD1, KD2). Habitats sampled were representative of the general river reach and included runs, pools and riffle/rapids if present. Mussel sampling was conducted on 41 days in 1999 and 33 days in 2000 from mid June to early October (Table 1).

A total of 3,464 quadrats were sampled along 160 transect lines at eight sites consisting of ten transects per site per year. A total of seven species in all were collected during 1999 and 2000 sampling; three species were habitat generalists, two species were indicative of small streams, one species was indicative of medium streams and small rivers, and one indicative of large rivers. Two species *Alasmidonta marginata* and *Lasmigona compressa* are listed as species of special concern in Wisconsin (Table 2). Species richness within reaches increased with increasing distance downstream, three species were found in the Michigamme Falls reach, five within the Twin Falls reach and six within the Kingsford reach. The number of live species found at sites ranged from 0 at MF2 in 1999 and 2000 to 6 at KD2 in 1999. The mean number of live species found per site was 3.4 in 1999 and 3.0 in 2000. A total of 1,101 live mussels and 476 dead shells were collected, *P. grandis* and *L. siliquoidea* were the most frequently collected mussels at all sites. The mean number of live mussels collected per site was highly variable between sites averaging of 73.8 in 1999 and 63.9 in 2000 and ranging from 0 at MF2 to 315 at TF4. Total biomass of live mussels collected at all sites was 46.3 kg. Mean mussel biomass averaged 2.9 kg per site in both 1999 and 2000. However, biomass was highly variable between sites ranging from 0 kg at MF2 to 11.7 kg at site TF4. Site TF4 had the highest number and biomass of mussels both years while site KD2 had the highest number of species (Table 3). No live mussels were collected during sampling at site MF2 in 1999 and 2000 or at TF2 in 2000 however, live mussels were observed in the vicinity of the sampling quadrats but their densities were too low to be collected during random sampling.

Mussel density per square meter was calculated for each quadrat and assessed relative to the distance from the OHWM for each site. Mussels were not evenly distributed from the bank to the center of the channel nor were they evenly distributed between habitat types (Figure 2). Mean mussel density for the combined sampling years was highest at site TF4 with 3.9 mussels/m^2 and lowest at site MF2 with 0.0 mussels/m^2 (Table 4). Mussel density for site TF4 ranged from 0.7 to 7.6 mussels/m^2 and peaked 4 m from the OHWM and was markedly reduced beyond 30 m from the OHWM (Table 5). Mussel density for the remaining sites peaked between 4 to 7 m from the OHWM and rapidly decreased beyond 10 m from the OHWM except for site MF1 which had a peak density at 16 m from the OHWM. No live mussels were found at site MF2 and only three *P. grandis* were found at site TF2, both sites experience extensive de-watering at base flows. Across all sites, few mussels were found within 3 m of the OHWM for both pool and run habitat unless there was sufficient depth to prevent de-watering at base flows.

Age and Size Structure

P. grandis and *L. siliquoidea* were the only mussel species abundant enough to plot age distribution and mean length at age. *P. grandis* ranged in age from 0 to 12 years (Figure 3) and *L. siliquoidea* from 0 to 17 years old (Figure 4). *P. grandis* and *L. siliquoidea* exihibited good age distribution when combined

across all sites. Estimation of survival rate and mortality rate were calculated from age composition for *P. grandis* and *L. siliquoidea* (Table 6). Survival rates for age 2 and older *P. grandis* were 69% in 1999 and 58% in 2000 (Figure 5). Survival rates for age 2 and older *L.siliquoidea* were 80% in 1999 and 78% in 2000 (Figure 6). Juvenile mussels less than 2 years old comprised 37 % and 33% of the *P. grandis* population and 36% and 26% of the *L. siliquoidea* population in 1999 and 2000 respectively (Table 7). The number of *P. grandis* beyond age 5 was sharply reduced indicating a change in recruitment or survival after 1994. The remaining species were collected in insufficient numbers to accurately plot age distribution indicating low recruitment to their populations. As for the remaining species, six *A. marginata* ranged from 4 to 12 years of age, 11 *A. ferussacianus*l ranged from 2 to 9 years, eight *F. flava* ranged from 2 to 4 years, 12 *L. compressa* ranged from 2 to 8 years, and five *L. costata*l ranged from 9 to 16 years old.

Growth curves for *P. grandis* and *L. siliquoidea* showed the same overall curvilinear growth pattern, with *P. grandis* having a faster growth in length and weight than *L. siliquoidea* (Figure 7). Fastest growth occurred in the first four years of life and declined thereafter. Abrasion of the periostracum was evident on many of the mussels collected, 17 % of mussels collected had 50% or greater erosion on the shell. Shell erosion was most prominent on the umbo portion of the shell then extending onto anterior and posterior regions of the shell. Abrasion was more prominent on older mussels and mussels located in swifter flows.

Habitat

The site means for habitat variables are given in Table (8). Depth and velocity were directly influenced by discharge from the upstream dams at each site. Sampling was conducted when discharge was considered within normal mean daily flow for the time of year, but varied between sites. Water levels below the dams varied daily as much as 1.1 m at MF, 0.36 m at TF and 0.46 m at KD sites (WEPCO data for summer 1997). Mean river width ranged from 26 m (TF2) to 141 m (KD1). Site TF4 was the deepest site sampled and site TF2 the shallowest. Site TF2 was nearly completely dewatered on a regular basis at voluntary minimum flow events except for a small trickle of water down the right center portion of the channel. Live *P. grandis* and *L. siliquoidea* were observed stranded and attempting to reach deeper water on several occasions especially after periods of prolonged high water followed by sudden flow changes down to voluntary minimums.

Suitable substrate for mussels decreased with increasing distance from the bank. The percentage of fine substrates were greatest in the first 10 m from the OHWM and decreased as the distance from the OHWM and bottom velocities increased. Fine and large gravel were the dominant substrate type at intermediate and center portions of the river at all sites. Fine and coarse sand substrates suitable for mussels, were observed in the center portions of the channel beneath gravel substrate, indicating that sediment starved water released from the dams had scoured away the available fine substrates. The percent of quadrats with armored substrate increased substantially with distance from the OHWM, only three mussels were found in the 343 armored quadrats sampled. Mussel presence was positively related to macrophyte density. Sites KD1 and MF1 had the greatest percentage of macrophytes; predominantly water celery (*Vallisneria americana*). Bottom water velocities were lower and the percentage of fine substrates greater within macrophyte beds. Site MF2 had the greatest percentage of algae covering the substrate.

Ten variables were statistically significant to the occurrence of live mussels. The best model for predicting the presence of live mussels includes variables related to water depth, velocity, substrate type and presence of macrophytes, with mussel presence increasing as depth increases, increasing percentages of finer substrates of sands, muck and fine wood and macrophytes (Table 9). The presence of mussels decreased with distance from bank, increasing water velocity, cobble substrate and substrate embeddedness. Model concordance was 79.3 percent providing a reasonable relationship of mussel

presence to available habitat from a biological aspect. Top water column velocity was strongly correlated to bottom water column velocity however both velocities were weakly correlated with distance from bank.

Discussion

Mussel species richness and density in the upper Menominee River appear to be substantially reduced from what would be expected in a large river system. Species richness and density varied considerably between the three reaches and between sites within reaches. Species richness within reaches increased with increasing distance downstream, three species were found below Michigamme Falls, five below Twin Falls and six below Kingsford. Quantitative sampling during this study produced greater species richness within two of the three study reaches compared to semi-qualitative sampling during preliminary studies in 1996 and 1997. Quantitative sampling captured the same three species, *P.grandis*, *L. siliquoidea* and *A. ferussacianus*, the same as semi-qualitative sampling below Michigamme Falls, while three additional species, *F. flava, L. compressa* and *L. costata* were collected below Twin Falls, and one additional species, *A. marginata* below Kingsford. Depletion curve methodology yields good estimates of species presence and proportional abundance for comparison among sites, but provides limited data on density or biomass that can be used for long term monitoring (Strayer et al. 1995, Smith et al. 1999). Within the Menominee River watershed, mussel species richness is considerably reduced above Sturgeon Falls Dam. Thirteen species were recorded below Sturgeon Falls during preliminary a study of which four were considered large river species, one medium streams, two small stream and seven were habitat generalist. Only one large river species, L. costata, was collected at KD2 during this study.

Historical information on fish and mussel distribution in the upper Menominee River prior to the 1970's is very limited, so historical patterns must be inferred from recent data. Several explanations could explain the current distribution of mussel in the upper Menominee River. One plausible explanation for current mussel distribution may be the result of past geology in the region. As glaciers receded, Sturgeon Falls and other waterfalls upstream may have been barriers to fish movement, thus accounting for the low mussel species richness observed in the upper reaches. Sturgeon Falls is considered a historical barrier to upstream fish movement in the Menominee River and many fish species from the lower river are absent from above, especially riverine specialist species (Becker 1983; EA Science and Technology 1987; Thuemler and Schnicke 1992). The distribution of mussel species is typically closely tied to the distribution and diversity of fish species (Watters 1993). The glochidia of freshwater mussels must parasitize certain fish species in order to complete their life cycle. Many of the mussels have only a specific fish host, while some may use multiple species as hosts (Watters 1994; Cumming and Mayer 1992). Fish play an important role in the upstream distribution of mussels, once the glochidia develop and fall off of the fish host upstream movement is limited. It is unlikely that a particular mussel species will be present if the host fish species is absent.

A second explanation for mussel distribution in the upper Menominee River is that some of the mussel species now restricted below Sturgeon Falls may have been present above, but were extirpated from the upper reaches by human impacts. Municipal and industrial pollution downstream of the cities of Iron River (MI), Iron Mountain (MI) and Niagara (WI) formally caused fishkill in the upper reaches (Thuemler and Schnicke 1992) that may have eliminated mussels such as *Amblema plicata, Elliptio dilatata, Ligumia recta* and *Lampsilis cardium* and their fish host species. Dams and waterfalls would have prevented fish movements and the transport of glochidia into the upper reaches allowing mussel species to recolonize.

Another possibility is that impoundments and flow regulation due to the operation of hydroelectric facilities have led to a decline in mussel species richness and their host fish species. Significant declines in mussel fauna as a result of damming have been well documented (Isom 1969; Williams et al. 1992) as

have declines below dams as a result of peaking hydropower operations (Layzer et al 1993). In addition to direct impacts on mussels, short-term flow fluctuations below daily peaking hydropower projects have been documented to have negative impacts on host fish species especially riverine specialist species (Kinsolving and Bain 1993). It is unlikely that any new species will enter the study area due to downstream dams preventing upstream movement of host fishes. I suspect that the altered flow patterns on the upper Menominee River have likely led to the depressed mussel species richness and density through a combination of factors. Changes in flow patterns may be affecting the distribution, abundance, and habitat use of host fishes thereby affecting mussels and that dramatic flow fluctuations have led to a decrease in suitable habitat for adult and juvenile mussels. Mussel species currently present in the study area should increase in number and biomass under more stable flows.

The distribution of mussels across the channel at each site was somewhat unusual. Mussels were concentrated at an intermediate distance from the banks, and were rare or absent from nearshore areas and also from the middle of the channel. In unregulated river reaches, mussels are usually common across the entire channel, whereas in reaches experiencing daily peaking they are often scarce along the margins of the channel but widespread throughout the intermediate and center zones. Lack of mussels at the edges is probably due to de-watering of some areas during the low-flow phase of the peaking cycle couple with dramatic fluctuations in velocity and depth in those nearshore areas that are not de-watered. Given adequate time, many mussels are capable of limited movement and will generally retreat towards deeper water as water levels recede. Current water flow changes on the Menominee River below the dams occur too rapidly to allow mussels safe retreat to deeper water as witnessed by stranding of mussels and fish at MF2 and TF2. Mussels can survive for short periods of time in dewatered areas if they can burrow down into the substrate to reach the water level however, larger substrate in many of the areas prevented mussels from being able dig in. Mussels unable to dig in are vulnerable to predation or desiccation. The absence of mussels from the edges of the Menominee sites is thus not unexpected, but their absence from the center of the channel is. Absence in the center is more difficult to explain, and may be caused by particularly high velocities that scour away fine sediments needed for mussels to burrow into. High velocities in the center of the channel have created an armored-like substrate and this substrate matrix may be impenetrable to mussels. Any mussels not able to dig into the substrate would be quickly washed away downstream especially juveniles. Suitable substrate for mussel colonization consisting of fine and coarse sands and loose fine gravel is limited in the center channel portions of the river. Aggradation is universal below dams as fine substrates are scoured but the reservoir and dam proper block upstream sources. High scour occurring at a critical time in the life stage of young mussels will prevent their colonization of the substrate. Under present flow conditions, loosely compacted fine sediments suitable for mussels is limited to areas near the inside of bends or protected by upstream obstructions big enough to create large areas of finer substrate. After flow changes occur in 2001, more stable flows should allow re-colonization of habitats currently being avoided by mussels where suitable substrate exists, but may not increase available habitat overall.

Acknowledgments

The following people helped to collect mussel data on the Menominee River: Corey Puzach and Shari Fanta. This study was funded in part by the Wisconsin Electric Power Company.

March 2004

SUMMARY

The Wisconsin Department of Natural Resources is evaluating how changes in flow regulation at hydroelectric dams on the Menominee River in northeastern Wisconsin will effect fish communities. This report summarizes fish and habitat conditions from 1996-1998, prior to flow regulation changes, which were implemented in 2001. Future sampling, scheduled to begin in 2007, will examine conditions in the river after the fish community has had time to adjust to the new flow regime. In 1996, eight permanent study sites were established within riverine portions of the uppermost 51.5 miles of the Menominee River, and these were sampled for fish and habitat once per year through 1998 using standardized techniques. Single reference sites on the St. Croix River (relatively unregulated) and on the Chippewa River (heavily regulated) in northwestern Wisconsin, where flow regulation did not change, were also sampled for fish and habitat in the same manner during the same time period. The eight Menominee River sites yielded a total of 36 species and 16,259 individuals over the three years of sampling, compared with 24 species and 720 individuals from the Chippewa River site and 36 species and 2,233 individuals from the St. Croix River site. The Menominee sites had 16 species in common with the Chippewa site and 21 in common with the St. Croix site. Smallmouth bass were the most common gamefish at all sites. The St. Croix site had three state-threatened species, river redhorse, greater redhorse, and gilt darter, but no threatened or endangered fishes were taken at the Menominee or Chippewa sites. Most fish and habitat variables were stable enough over time to be useful for assessing responses to flow regime changes in the Menominee. Year-to-year variation at individual sites usually did not exceed 20% for fish species richness, 15% for fish diversity and evenness, 30% for the index of biotic integrity (IBI) score, and 20% for habitat characteristics. However, fish number and biomass had annual variation that often surpassed 100%, and these two measures will be less sensitive indicators of fish community response. Fish community characteristics had a strong longitudinal pattern in the Menominee River. The four downstream-most sites, located in the lower subarea where flow regulation was not as pronounced, had higher biomass, species richness, diversity, and IBI scores than the four upstream-most sites, located in the upper subarea where flow regulation was much greater. In particular, the abundance, biomass, and species richness of riverine specialists (obligate river dwellers) was much higher in the lower subarea. Four riverine specialists, northern hog sucker, silver redhorse, golden redhorse, and blackside darter, were common in the lower subarea but absent from the upper subarea. These species may have always been absent from the upper area because waterfalls prevented post-glacial colonization, or they may have been present historically but eliminated because of water pollution or flow regulation. Habitat varied among sites, but did not differ between the upper and lower subareas. The fish community at the Chippewa site was most similar to the community at Menominee River sites in the upper subarea whereas the St. Croix fish community was most similar site to Menominee River sites in the lower subarea. Based on findings to date, the fish community in the lower subarea will probably show less of a response to changes in flow regime than the upper subarea. The fish community in the upper subarea has great potential for improvement, but this potential may not be fully realized because dams and waterfalls will prevent species from entering the subarea in response to the changes in flow regime.

INTRODUCTION

In 1995, the Wisconsin Department of Natural Resources (WDNR) began a research study to quantify the effects of hydroelectric power dams on biological communities in Wisconsin's larger rivers (Low 1995). This study focused on riverine fish and had two phases:

I. Comparisons between river reaches with flows heavily regulated by dams and river reaches with few dams (1995-2004).

1. Intensive comparison between the heavily regulated Chippewa/Flambeau River system and the relatively unregulated St. Croix River system (Piette 2004).

2. Extensive statewide comparison among river reaches for the development of an index of biotic integrity based on fish communities, to be used for the rapid bioassessment of human impacts, including flow regulation, on large river ecosystem health (Lyons et al. 2001).

II. Evaluation of the changes in biota following a shift in flow regulation patterns in the Menominee River system (1996-2010) (This report).

The study emphasized both the site-specific effects of flow regulation from individual dams and the system-wide cumulative effects of riverine habitat modification and fragmentation from multiple dams and impoundments.

Phase II of the study, the subject of this report, has a before-and-after-control-impact (BACI) design (Underwood 1994). Intensive sampling of the biota of the Menominee River system took place in 1996-1998, before shifts in flow regulation in 2001, and are scheduled again for 2007-2010, after the biotic community has had a chance to adjust to the shifts in flows. A site on the relatively unregulated St. Croix River and another site on the heavily regulated Chippewa River were sampled as references ("control") for comparison with the Menominee River ("impact") sites. Flow regulation will not change at these two sites over the study period.

This final report summarizes results from the 1996-1998 sampling in the Menominee River system, the "before" portion of Phase II. It serves to close out the study initiated in 1995. A separate study proposal will be developed to guide the "after" portion of Phase II in 2007-2010.

STUDY AREA

The primary study area for phase II encompassed the upper portion of the Menominee River in northeastern Wisconsin, from Pemene Falls (River Mile (RM) 67.1) upstream 51.5 miles to the source of the Menominee at the confluence of the Michigamme and Brule rivers (RM 118.6) (Figure 1). The Menominee River forms the border between Wisconsin and Michigan and empties into Green Bay, Lake Michigan. Within the study area were five

hydroelectric dams: Sturgeon Falls (RM 83.0), Little Quinnesec (Niagara)(RM 91.4), Big Quinnesec (RM 96.0), Kingsford (Henry Ford)(RM 101.5), and Twin Falls (RM 107.9) (Thuemler and Schnicke 1992). Just upstream of the start of the Menominee River were Michigamme Falls Dam, located on the Michigamme River at RM 0.2, and Brule Island Dam, located on the Brule River at RM 1.7. Flow through the Michigamme Falls Dam was heavily influenced by flows from three additional dams, Peavy, Hemlock, and Way, located further upstream in the Michigamme River system. Three waterfalls remained within the primary study area (several others were inundated by the hydroelectric dams): Pemene, Quivers (RM 72.9), and Sand Portage (Pier's Gorge)(RM 89.6).

The primary study area could be split into two subareas based on the shifts in flow regulation. The upper subarea extended from the Little Quinnesec Dam upstream to the Michigamme-Brule confluence (27.2 miles; Figure 1). This subarea was influenced by daily peaking operations at the Michigamme Falls, Twin Falls, Kingsford, and Big Quinnesec dams (Thuemler and Schnicke 1992). Prior to 2001, peaking caused daily variations of over 3.3 ft in river depth, and in some areas, particularly immediately below the Michigamme Falls Dam, extensive areas of the channel were alternately dewatered and inundated over a 24-hour period. Peaking operations at all four dams changed in 2001, when a new operating regime was initiated. This regime mandated run-of-river flows during the spring, and for the rest of the year allowed peaking operations only if the daily maximum flow did not exceed twice the daily minimum. The new regime resulted in reduced daily fluctuations in flow and generally higher minimum flows. The lower subarea extended from Pemene Falls to the Little Quinnesec Dam (23.9 miles). This subarea was influenced by daily peaking operations at the Little Quinnesec Dam, although variations in depth and current were much less than in the upper subarea. Since 2001 daily fluctuations in discharge from the Little Quinnesec Dam have been "re-regulated" at the Sturgeon Falls Dam to provide more stable flows downstream.

Based on reconnaissance in 1996, we established eight sampling sites in riverine segments within the primary study area (Table 1, Figure 1). At these sites data on fish and habitat were collected (only five of the sites were sampled in 1996). Each site contained one continuous mile of riverine (i.e., non-impounded) habitat. Locations were chosen based on proximity to dams and waterfalls and ease of access. In the lower subarea, two sites were between Quivers and Pemene Falls (QF1 and QF2) and two were below Sturgeon Falls Dam (SF1 and SF2). In the upper subarea, one site was below Kingsford Dam (KD1), one was below Twin Falls Dam (TF1), and two were below Michigamme Falls Dam (MF0 and MF1). Insufficient riverine habitat existed for a sampling site below the Big Quinnesec Dam, and we chose not to sample the riverine area below Little Quinnesec Dam because of concerns about the confounding impacts of historical point-source pollution problems. Although they appeared to be riverine, analyses of flow gage data indicate that sites TF1 and KD1 experienced backwater effects from impoundments that were located just downstream (Tom Thuemler, WDNR, retired, personal communication). The Menominee River had a basin area of 1,760 square miles at MF0, the upper most site, and 3,100 square miles at QF2, the lowermost site. Mean annual flows were 1,797 ft^3/sec at TF1, 2,187 ft^3/sec below the Little Quinnesec Dam, 2,519 ft^3/sec at SF1, and 2,895 ft^3/sec below

Pemene Falls, 4.0 river miles below QF2 (Waschbusch et al. 2003). Conductivities during sampling ranged from 120-250 S/cm (WDNR, unpublished data).

Two reference sites were established in northwestern Wisconsin, one on the relatively unregulated St. Croix River, where daily peaking flows were absent, and the other on the Chippewa River below Cornell Dam, where major daily peaking occurred (Table 1, Figure 1). The St. Croix River forms the border between Wisconsin and Minnesota and the Chippewa River is wholly within Wisconsin. Both rivers empty into the Mississippi River. The two reference sites were sampled for fish and habitat in the same manner and during the same years as the Menominee River sites. At the St. Croix study site (MSC5; RM 94.8), the basin area was 4,000 square miles, and the nearest dams were 62.4 river miles upstream (Gordon Dam) and 40.0 river miles downstream (St. Croix Falls Dam). Mean annual flows were 1,322 ft^3/sec at the town of Danbury, 26.3 river miles upstream from the study site, and 4,398 ft^3/sec at St. Croix Falls, 40.2 river miles downstream (Waschbusch et al. 2003). Conductitives during sampling averaged about 150 S/cm (WDNR unpublished data). At the Chippewa River study site (MC2; RM 95.5), basin area was 4,780 square miles, and the nearest dams were 2.3 river miles upstream (Cornell Dam) and 8.2 river miles downstream (Jim Falls Dam). Mean annual flow was 5,117 ft^3/sec at the city of Chippewa Falls, 23.3 river miles downstream, and 1,818 ft^3/sec near the town of Bruce on the Flambeau River (a Chippewa River tributary larger than the Chippewa where the two met at RM 114.0), 24.5 river miles upstream. Flows at the study site fluctuated greatly because of peaking operations at the Cornell Dam. Depths varied by more than 3.3 ft and extensive areas of the channel were dewatered and inundated on a daily basis. Conductivites during sampling averaged about 90 S/cm.

METHODS

Fish

Fish were sampled throughout each study site once per year between early June and late August. Two electrofishing techniques were employed, a boat-mounted "mini-boom" shocker and a pre-positioned bottom electrofishing grid. The mini-boom, which was most efficient for medium- to large-bodied fishes, was a standard WDNR unit, with a 3500 W AC generator that passed output through a transformer and pulsar unit to provide pulsed-DC current (60 Hertz, 25% duty cycle). Power output was kept between 7.5-10.5 A and 275-400 V for a total of about 3000 W. The anode was a single boom with a Wisconsin ring and 12-16 droppers, and the aluminum boat hull was the cathode. A single netter with a 0.75-inch stretch-mesh dip net attempted to catch all fish observed (Lyons et al. 2001). The mini-boom was operated in a downstream direction over the entire length of each station (one mile). One shoreline and the middle of the channel were shocked during the daytime, and the remaining shoreline was shocked at night, for a total of three miles of mini-boom sampling. Preliminary studies in 1995 on the St. Croix, Chippewa, and Wisconsin rivers indicated that one mile of daytime shoreline shocking gave a reasonably accurate and precise picture of fish community structure and composition, but that night shocking yielded great numbers and biomass and a wider size range of fish. The mid-channel shocking was included to capture fishes not closely associated with shoreline habitat.

Electrofishing grids (Bain et al. 1985) were used to capture small-bodied fishes in shallow shoreline habitats that could not be adequately sampled with the mini-boom. The grids were 6.6 X 26.2 ft, covering a rectangular bottom area of 173 ft^2. The long axes of the grid were made of steel wire and served as the electrodes; the ends of these wires were joined by ropes to form a rectangle. The electrodes were powered by a 3500 W generator that produced AC current at 7-11 A and 250-500 V. Girds were positioned on the bottom within 1 foot of shore in water less than 3.3 ft deep, with their long axis parallel to the shoreline. Grids were set and then left undisturbed for at least 15 minutes prior to activation, which allowed sufficient time for small fishes to recover from any disturbance caused by the setting of the grid. Power was then applied to grids for 30 seconds, and all stunned fish were collected with dip nets. In fast current, a small-mesh seine was held just downstream of the grid during sampling to catch drifting fish. Grids were set in pairs (each member of the pair separated by 33 ft) at 13 randomly chosen locations over the entire length of each one-mile site, for a total of 26 grid samples per site. Preliminary work in 1995 on the St. Croix and Wisconsin rivers indicated that 26 grid samples gave a reasonably accurate and precise estimate of the community structure and composition of small shoreline fishes.

All captured fishes were identified to species, counted, and weighed in aggregate. Scientific names are given in Appendix 1. Gamefish (listed in Appendix 1) were measured for total length to the nearest mm. Scales were taken from a subsample of smallmouth bass for aging, but these aging data have not yet been fully analyzed and are not included in this report. Voucher specimens of difficult to identify or rare species were preserved for later examination in the laboratory, but most captured fish were returned to the river after processing.

The following summary statistics were calculated for each site for all miniboom and grid samples pooled, except as noted (see Fausch et al. 1990 for formulae): total number of fish, total biomass, total species richness, species diversity (Shannon index) based on number and on biomass, evenness based on number and on biomass, index of biotic integrity (IBI) score and rating (based only on daytime shoreline miniboom sample; Lyons et al. 2001), and the number of individuals, biomass, and species richness of gamefish species and of riverine specialist species (require riverine habitat for entire life cycle, Kinsolving and Bain 1993; listed in Appendix 1).

Habitat

The following variables were measured or visually estimated for each grid using standard procedures from Simonson et al. (1994): stream channel macrohabitat type (seven categories), shoreline vegetation/land use type (seven categories), cover types (four categories), cover densities (four levels), amounts of bottom substrates (seven types), depths (six positions), and current velocity (three positions). Mean values or percentage frequency of occurrence from all 26 grids were determined for each habitat variable for each site.

RESULTS

Fish

Over the three years of the study, the eight Menominee River sites yielded a total of 36 fish species and 16,259 individuals. Recall that only five of the eight sites were sampled in 1996. The Chippewa River reference site (MC2) produced 24 species and 720 individuals and the St. Croix reference site (MSC5) 36 species and 2,233 individuals. The Menominee River had 16 species in common with the Chippewa and 21 with the St. Croix. No state threatened or endangered species were collected from the Menominee or Chippewa River sites, but three Wisconsin threatened species, river redhorse, greater redhorse, and gilt darter, were captured in the St. Croix (Appendices 1-3).

Variation among years – In the Menominee River, year-to-year variation at individual sites was high for two of the fish summary statistics, but limited for the rest. The total number of fish and total biomass fluctuated substantially (> $\pm$100%) among years at some sites, but values for species richness, diversity, evenness, and IBI score and rating were generally much more stable (Table 2). For seven of the eight Menominee River sites the total number of fish was much greater in 1998 than in other years because of the catch of large numbers of young-of-the-year (YOY) white sucker and smallmouth bass (Tables 3-5; Appendices 1-3). However, for only four of these sites was total biomass highest in 1998 (Table 2). At most sites, annual variation did not exceed three species (< $\pm$20%) for species richness, 0.3 units (< $\pm$15%) for diversity, and 0.1 units (< $\pm$15%) for evenness. Index of biotic integrity (IBI) scores usually changed by less than 15 points (< $\pm$30%) and the overall quality rating remained constant across the three years. Major exceptions to this pattern occurred at Menominee River sites KD1 and MF0, where particularly high catches of YOY white sucker in 1998 dropped diversity values based on number by 1.3 to 1.5 units and evenness based on number by 0.5 to 0.6 units. At site KD1 diversity and evenness based on biomass changed little in 1998, but at MF0 diversity based on biomass increased by 0.7 units and evenness based on biomass by 0.3 units. The IBI score at Menominee River site MF1 jumped by 25 points and the quality rating improved from poor to fair in 1998 as a consequence of an elevated number of YOY smallmouth bass and the capture of longnose sucker and brook trout. Longnose sucker and brook trout are intolerant coldwater species not normally found in the warmwater Menominee.

Subsets of the total species pool varied in essentially the same manner (Table 2). For gamefish species, there were substantial year-to-year fluctuations in total number at all sites and in biomass at about half the Menominee River sites (Table 2). However, species richness at the sites did not vary by more than three species. Most of the differences over time in number and biomass were caused by changes in YOY smallmouth bass numbers, particularly the relatively high catches in 1998 (Tables 3-5). For riverine specialist species, total number and biomass fluctuated substantially at about half the sites, but species richness did not vary by more than three species (Table 2).

The St. Croix and Chippewa River reference sites had annual variation patterns generally similar to the Menominee River. Numbers and biomass of all fish, gamefish, and riverine specialists varied substantially over time, but

diversity, evenness, and IBI scores and ratings changed relatively little (Table 2). Species richness of all species, gamefish, and riverine specialists was stable across years in the St. Croix but was higher in 1998 than in 1996 or 1997 in the Chippewa.

Variation among sites – In the Menominee River, most of the fish summary statistics differed between the upper and lower subareas (Table 2). With but a few exceptions, total biomass, total species richness and diversity were higher in the four sites in the lower study subarea (QF2, QF1, SF2, SF1) than in the four sites in the upper subarea (KD1, TF1, MF1, MF0). Index of biotic integrity ratings were always excellent in the lower subarea sites but usually poor and never better than fair in the upper subarea sites. Total number of fish and evenness did not show as clear a difference between the two subareas, although the lowest values occurred in the upper subarea. There were no apparent longitudinal trends in summary statistics within either subarea.

Number of fish, biomass, and species richness differed between the upper and lower subareas for riverine specialists but not for gamefish (Table 2). For riverine specialists, all three summary statistics were much higher in the lower subarea. In particular, biomass of riverine specialists was always at least 1000 times greater in the lower subarea than the upper. Four riverine specialist species, northern hog sucker, silver redhorse, golden redhorse, and blackside darter, were consistently common in the lower subarea sites, but absent from the upper subarea sites (Appendices 1-3). Hornyhead chub was the only riverine specialist species taken at all eight sites. For gamefish, there were no longitudinal trends in number of fish, biomass, or species richness, nor any clear differences between the upper and lower subareas. The highest number and biomass occurred at site TF1 in the upper subarea. Smallmouth bass were the most numerous gamefish and occurred at all eight sites. Rock bass and walleye were also captured at all sites, and northern pike were found at all sites except MF0.

Most of the fish summary statistic values for the two reference sites overlapped with those of the Menominee sites (Table 2). Values for the Chippewa site always fell within the range of Menominee site values except in 1996, when total species richness and diversity based on number were lower than Menominee values. Chippewa values for riverine specialist number, biomass, and species richness were higher than values from the upper subarea of the Menominee but lower than values from the lower subarea. Chippewa IBI scores and ratings (poor to fair) were similar to scores and ratings for the upper subarea of the Menominee. The St. Croix site consistently had the highest values for total species richness, diversity, and riverine specialist species richness. However, values for total number of individuals, total biomass, evenness, number and biomass of gamefish, and number and biomass of riverine specialists usually fell within the range of Menominee values. St. Croix values for IBI score and rating (always excellent) and number and biomass of riverine specialists were similar to values from the lower subarea of the Menominee and higher than values from the upper subarea. Among riverine specialist species, the St. Croix and Chippewa sites both had northern hog sucker, silver redhorse, and blackside darter (Appendices 1-3). The St. Croix

site also had hornyhead chub and golden redhorse, but these two species were not captured at the Chippewa site. The smallmouth bass was the most common gamefish species at both the Chippewa and St. Croix sites, but the two reference sites usually had smaller numbers of legal-sized smallmouth bass than the Menominee sites (Table 3-5). Rock bass and walleye occurred at both the St. Croix and Chippewa sites, but northern pike were encountered only at the St. Croix site.

Habitat

Habitat was collected only from shallow, near-shore margins of each study site. All sites had shorelines of natural vegetation and bottoms of natural substrates with a range of cover types.

Variation among years – In the Menominee River, year-to-year variation in most habitat characteristics was low (Table 7). Macrohabitat classifications were stable over time, and depths and current velocities at sampling points changed relatively little. Percentage measures of shoreline vegetation, cover, and substrate usually fluctuated less than 20%. Major exceptions were for site SF1, where relative amounts of large woody debris, boulder, and overhanging vegetation cover shifted from 1996 to 1997, and for sites QF2, SF2, and SF1 where percentages of forest shoreline increased substantially from 1997 to 1998.

The Chippewa and St. Croix reference sites also had relatively stable habitat values, and variation in most habitat characteristics was comparable to that observed in the Menominee (Table 7). In the St. Croix and Chippewa, as in the Menominee, habitat variables usually changed less than 20% from year to year. At the Chippewa site the relative amounts of grass shoreline decreased and forest shoreline increased by more than 20% between 1996 and 1997, and the relative proportions of large woody debris and boulder cover fluctuated substantially over all three years. In the St. Croix, the amount of grass shoreline declined and forest increased from 1997 to 1998. At both reference sites, macrohabitat classifications varied more than in the Menominee, with values in 1997 distinct from 1996 and 1998, which were more similar to each other.

Variation among sites – In the Menominee River there were no clear geographic patterns in habitat conditions (Table 7). Habitat varied among sites, but no longitudinal trends were evident, and values for sites in the lower subarea did not differ consistently from values in the upper subarea. Over all eight sites, pool habitat was scarce. Deep run was present at all sites, and sites QF1, SF2 TF1, MF1, and MF0 also had substantial shallow run/riffle habitat. Bank vegetation for all eight sites was predominantly forest, although grass and shrub banks also occurred. Cover at all sites was provided in the form of large woody debris, boulders, and overhanging vegetation. Sand was a common substrate at all sites. At sites QF2, QF1, SF1, and KD1 silt was common, whereas at SF2, TF1, MF1, and MF0 gravel and rubble/cobble were common.

Habitat conditions at the St. Croix and Chippewa reference sites were generally similar to conditions at the Menominee sites (Table 7). Both sites had predominantly forested banks with substantial amounts of grass banks. Boulders and large woody debris were important cover types, and sand and rubble/cobble were major substrates. The Chippewa site had predominantly deep run and shallow run/riffle macrohabitat and substantial gravel substrate. Differences between the reference sites and the Menominee were the presence of pool macrohabitat at the Chippewa and particularly the St. Croix sites, the scarcity of overhanging vegetation cover at both reference sites, the occurrence of substantial aquatic vegetation cover at the St. Croix site, and the greater amounts of boulder substrate and cover at both reference sites.

DISCUSSION

Variation among years

Fish and habitat variables appeared to be sufficiently stable over time to be useful in assessing responses to changes in flow regime in the Menominee River. Most variables fluctuated by 15-30% over the first three years of the study, prior to reductions in peaking flows that were initiated in 2001. Number and biomass of fish changed by a much greater amount from year to year, often more than 100%. Abundance and size structure of smallmouth bass also fluctuated widely. Given how much they changed annually even in the absence of flow changes, number and biomass of fish and smallmouth bass population characteristics will be less sensitive indicators of fish community response to flow regulation change than will the other fish variables. The observed levels of variation are typical of fish and habitat data from Wisconsin rivers and were probably caused by a combination of sampling error and natural fluctuations in fish and habitat conditions at the sites (Simonson et al. 1994; Lyons et al. 2001).

Variation among sites

Strong longitudinal patterns were evident in the fish community within the Menominee River. The upper subarea, where flow regulation was greatest, had lower total fish number, biomass, diversity, and biotic integrity than the lower subarea, where flow regulation was lesser. Much of the difference between subareas was caused by great disparities in the species richness, abundance, and especially biomass of riverine specialist species; riverine specialists such as northern hog sucker, silver redhorse, golden redhorse, and blackside darter were common in the lower subarea, but absent in the upper. Interestingly, the gamefish portion of the fish community differed little between the two subareas.

The differences in fish communities between the upper and lower subareas could be due to natural factors. Sturgeon Falls was a historical barrier to upstream movement by lake sturgeon and perhaps other fishes migrating out of Green Bay (Thuemler and Schnicke 1992). It and other waterfalls may also have served as barriers to upstream movements of colonizing fish species as glaciers receded from what is now northern Wisconsin and the upper peninsula of Michigan, thus causing the absence of certain species in the upper subarea.

Unfortunately, data from prior to the 1970s on fish in the upper portion of the Menominee River are very limited, so historical distribution patterns must be inferred from current data. Judging from present fish distribution patterns (this study; Becker 1983; EA Science and Technology 1987; Thuemler and Schnicke 1992; Greg Seegert, EA Science and Technology, Deerfield, Illinois, personal communication), Sturgeon Falls may have been the historical upstream limit for northern brook lamprey, northern hog sucker, and perhaps green sunfish; Sand Portage Falls may have been the upstream limit for rosyface shiner and silver redhorse; and Little Quinnesec Falls may have been the upstream limit for golden redhorse, shorthead redhorse, and blackside darter.

An alternative explanation for current fish distribution patterns is that at least some of the species now restricted to the lower subarea may have historically occurred in the upper subarea as well, but disappeared because of human impacts. Municipal and industrial pollution formerly caused fish kills downstream of the cities of Iron River (MI), Iron Mountain (MI), and Niagara (WI) (Thuemler and Schnicke 1992), and could have eliminated fish species such as rosyface shiner, northern hog sucker, silver and golden redhorse, and blackside darter that are sensitive to poor water quality (Lyons et al. 2001). Dams and waterfalls would have prevented these species from recolonizing the upper subarea after water quality was improved in the 1970s and 1980s. Another possibility is that impoundment and flow regulation from dams contributed to the disappearance of riverine specialist fish species. By definition, riverine specialist fish species are absent from impoundments. Kinsolving and Bain (1993) found that riverine specialist fishes were particularly sensitive to short-term flow fluctuations and tended to avoid river areas influenced by daily hydropower peaking.

Habitat conditions did not vary longitudinally and were not closely related to fish community structure in the Menominee River, suggesting that factors other than habitat were of primary importance in determining fish community characteristics. For example, site SF2, which had predominantly rocky substrates, had a fish community similar to site SF1, which had predominantly fine (silt and sand) substrates. Site MF1 had relatively high cover density and variety, and thus some of the best fish habitat, and yet had a relatively low number, biomass, and diversity of fish.

Although located in a different part of the state, the reference sites seemed to be reasonably similar to the Menominee River sites in terms of fish communities and habitat. There were many fish species in common between the Menominee River and the St. Croix and Chippewa sites. The St. Croix site had the richest fauna, but values for most measures of community structure overlapped. The gamefish faunas of the Menominee sites and the two reference sites were similar. Habitat conditions also overlapped substantially among sites, although pool habitat was common only at the two reference sites. The Chippewa site, which had heavily regulated flows, had a fish community most similar to that of the highly regulated upper subarea of the Menominee River, whereas the St. Croix site, which had

unregulated flows, had a community most similar to that of the lower subarea of the Menominee River, where flows were less heavily regulated than in the upper subarea.

Predicted responses to flow regime changes in the Menominee River

Based on results gathered thus far, two predictions can be made concerning fish community changes in the Menominee River in response to the reduced daily peaking flows begun in 2001. First, changes in the lower subarea of the Menominee River are likely to be smaller than changes in the upper subarea. In the lower subarea, the modifications in flow regime since 2001 have been less dramatic than in the upper subarea, and the fish community in the lower subarea was already in relatively good condition in 1996-1998 and had less room for improvement. Of the fish variables that have been measured, species richness and diversity have the greatest potential to increase in the lower subarea.

Second, the upper subarea has great potential for improvement, but may not fully realize this potential because of isolation. The modifications in flow regime in the upper subarea since 2001 have been large, and the fish community there in 1996-1998 was well below expectations for a relatively unregulated system. Species richness and diversity, particularly for riverine specialist species, and IBI scores have the greatest room for improvement. However, many species that might survive or even thrive under the new flow regime are blocked from entering the upper subarea by dams and waterfalls. Riverine specialist species already present in the upper subarea, such as hornyhead chub and longnose dace, will probably increase in abundance in response to the reduced peaking flows. However, other riverine specialists that would likely benefit from reduced peaking, such as northern hog sucker, silver redhorse, golden redhorse, and blackside darter, cannot access the upper subarea. Thus, barring direct introductions of currently absent riverine specialists, the upper subarea fish community will not change as much as it would if there were no barriers to upstream fish movement.

ACKNOWLEDGMENTS

I thank Ed Avery, Tom Baumgartner, Connie Boehlke, Mary Botzet, Matt Keefer, Kent Niermeyer, Jerry Peterson, and Randy Piette for collecting the data. Dave Michaud, Tom Thuemler, and Dennis Geary provided information on potential sampling locations, access points, and hydropower dam operating regimes. This study was funded in part by a gift from Wisconsin Electric Power Company to the Wisconsin Department of Natural Resources (activity code SSIK), and Federal Aid in Sport Fish Restoration, project F-85-P, study SSDM.

Table 1. Location of sampling sites. All sites were one mile in length; the river mile and location refer to the downstream end of the site.

Code	River Mile	Location
Menominee River sites		
QF2	68.3	4.6 miles below Quivers Falls and 1.2 miles above Pemene Falls, centered on Faithorn Landing (MI)
QF1	71.6	1.3 miles below Quivers Falls, 2.8 miles above Faithorn Landing (MI)
SF2	75.6	7.4 miles below Sturgeon Falls Dam, 2.7 miles above Quivers Falls, 1 mile below Saler Landing (WI)
SF1	81.6	1.4 miles below Sturgeon Falls Dam, 1.3 miles below Sturgeon Falls Dam Landing (MI)
KD1	99.9	1.6 miles below Kingsford Dam, 1.9 miles above Aurora Landing (WI)
TF1	106.7	1.2 miles below Twin Falls Dam, 2.4 miles above Kingsford Flowage Landing (MI)
MF1	116.8	2 miles below confluence of Michigamme and Brule rivers, 2.0 miles below Michigamme Falls Dam, and 1.6 miles above landing (WI)
MF0	118.0	0.8 miles below confluence of Michigamme and Brule rivers, 1.0 miles below Michigamme Falls Dam (site extends 0.2 miles into Michigamme River to the base of the dam)
Reference sites		
MC2	95.5	Chippewa River (WI), 2.3 miles below Cornell Dam, 2.8 miles above Willow Island Landing (Old Abe Lake)
MSC5	94.8	St. Croix River (WI/MN), 0.2 miles above Snake River mouth (MN), 0.3 miles above Soderbeck Landing (WI)

Table 2. Number of individuals, biomass (lbs), species richness, diversity, evenness, and index of biotic integrity (IBI) score and rating for all species of fish, and number of individuals, biomass, and species richness for gamefish and riverine specialist species captured from study sites during 1996-1998. "NS" indicates not sampled. Ratings for the IBI score are "E" = excellent, "F" = fair, and "P" = poor. All values are for the combined catch of the miniboom and grid shockers, except for the IBI value and score, which is based on the daytime shoreline miniboom shocking only.

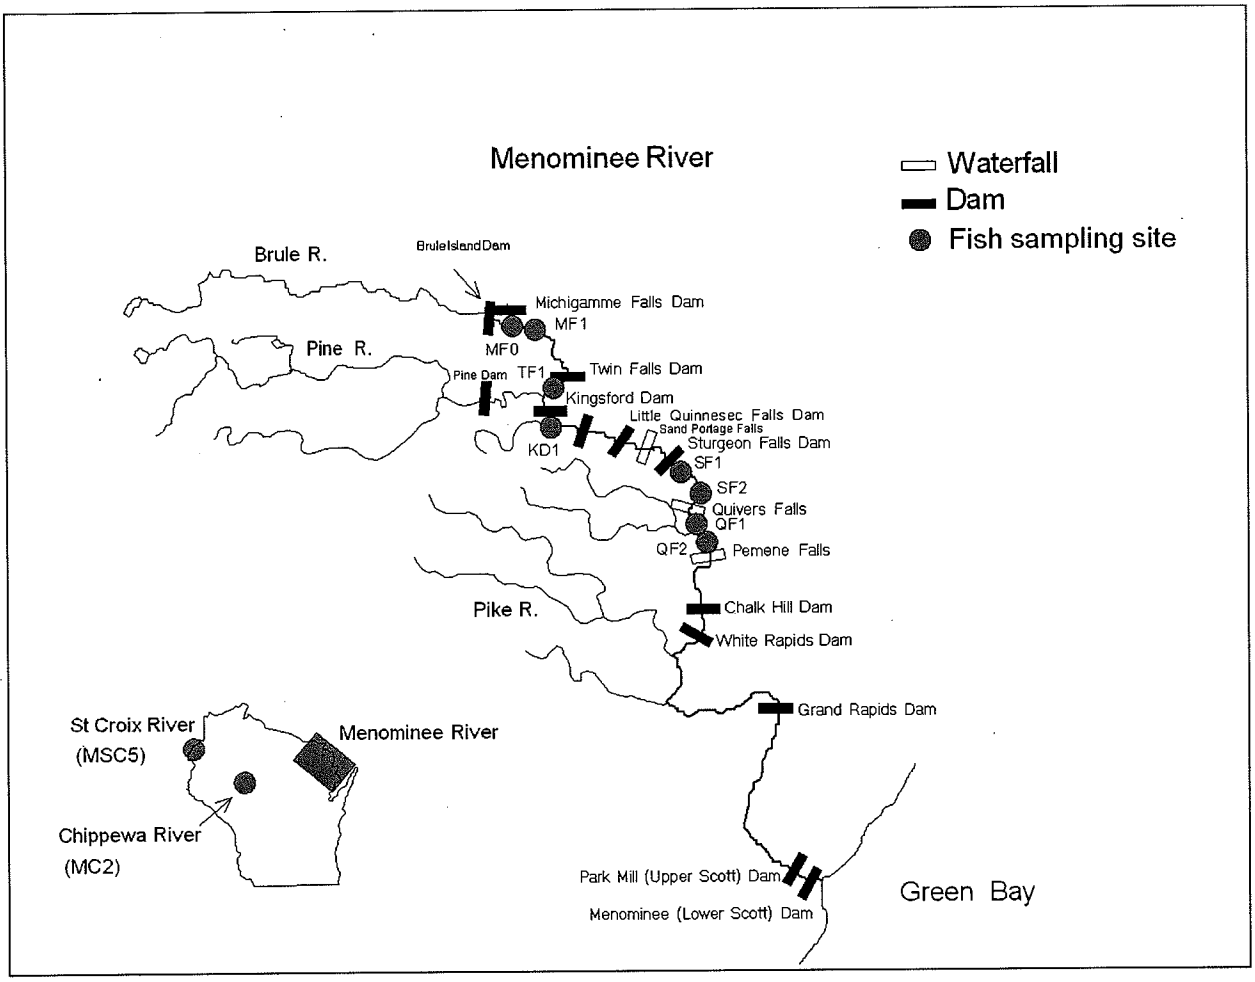
Figure 1. Map of Menominee River showing study sites, dams, and waterfalls. The inset map of Wisconsin shows the location of the St. Croix River and Chippewa River reference sites.



Appendix 1. Fish species captured during 1996 (combined miniboom and grid sampling) from the study sites. An "R" after the scientific name indicates a riverine specialist species, a "G" a gamefish species, and a "T" a state of Wisconsin threatened species. Menominee River sites QF1, TF1 and MF0 were not sampled in 1996.

Screening Level Risk Evaluation

Because we care
100% recycled paper produced by wind power energy

Appendix Q Screening Level Risk Evaluation

The following outlines a risk evaluation for the constituents detected in the Riverside Disposal Area (RDA) soil data. The methodology is consistent with guidance from the U.S. Environmental Protection Agency (U.S. EPA) and the Michigan Department of Environmental Quality (MDEQ). Specifically, MDEQ (1998a) exposure assumptions or constituent-specific parameters were used unless more recent U.S. EPA guidance was available. The deviations with the MDEQ guidance are noted below.

Data

The available data were reviewed and compared with the MDEQ Residential Direct Contact Criteria (DCC) for soil (1998b). All but three of the samples were detected at concentrations less than the residential DCC for soil. The three exceedences were sample SSRIV-1, SSRIV-7, and SSRIV-10. The first two had arsenic concentrations of 8.5 milligrams per kilogram (mg/kg) and 16 mg/kg, respectively, exceeding the residential DCC of 6.6 mg/kg. Sample SSRIV-10 contained lead (detected at 610 mg/kg) in excess of the residential DCC of 400 mg/kg. All of the soil samples contained constituent concentrations less than the industrial DCC indicating there is no risk to industrial workers from direct contact exposure to the constituents in soil. Based on this analysis, potential exposure to arsenic and lead were evaluated further.

Exposure Assessment

The RDA was closed, is currently fenced, and is covered by vegetation. Individuals should have no reason to be on the property. However, it is possible that a trespasser could walk across the property. Near the RDA are both a residential neighborhood and a school. It is possible that a child attending the Woodland Elementary school could walk across the RDA on their way to or from school. Therefore, this analysis focused on the potential exposure of a child attending Kindergarten through Fifth Grade at the school.

Several exposure assumptions were used to evaluate this potential exposure. The MDEQ (1998a) equations for industrial exposure were consulted. MDEQ evaluates only ingestion and dermal (skin) contact for soil direct contact exposures. Although the site is well vegetated, it is possible that fugitive dust emissions could occur from the RDA. Therefore, the MDEQ equations were not used in this evaluation and U.S. EPA (1996) equations were used instead. It should be noted that the MDEQ combined exposure evaluations into one equation and U.S. EPA uses three. The U.S. EPA approach allows the risk assessor to identify the primary exposure route contributing to risk.

The child was assumed to range in age from 5 years to 10 years, for a 6 year exposure period. MDEQ (1998a) does not provide body weights or skin surface areas for children these ages; therefore, U.S. EPA (1997) guidance was consulted to obtain appropriate exposure parameters. A body weight of 37.5 kilograms (kg) was calculated based on the 95th percentile of body weights of male children ages 5 through 10 (U.S. EPA, 1997). The skin surface area was calculated using the rationale used by MDEQ in their guidance (1998a). Twenty-five percent of the average of the 50th percentile for the total skin surface area for male children (9,742 square centimeters [cm^2]) was calculated to be 2,435 cm^2. This corresponds to the hands, arms, legs, neck, and head (MDEQ, 1998a).

Soil ingestion is greatest for young children. Since the potentially exposed individuals would not be playing at the RDA, but would only be walking across the RDA, a soil ingestion rate of 50 milligrams per day (mg/day) was selected. U.S. EPA (1997) recommends the use of a median soil ingestion rate of 100 mg/day for young children and 50 mg/day for older children and adults. The use of the 50 mg/kg is consistent with this recommendation.

Because we care
100% recycled paper produced by wind power energy

As the child walks across the property, soil may be kicked up and adhere to the child's skin. The MDEQ (1998a) uses a soil adherence factor of 1 milligram per square centimeter (mg/cm^2). This value was obtained from a U.S. EPA (1991) reference. U.S. EPA (1997) provides soil adherence data for various outdoor activities. The data were reviewed and the soccer player and groundskeeper data seemed to correspond to the level of exposure that the individual at the RDA might encounter. These values were less than or equal to 0.1 mg/cm^2. As a conservative measure, a value of 0.2 mg/cm^2 was selected since this value corresponds to a slightly higher level of exposure, although this level of exposure is not likely to occur for the trespasser at the RDA.

MDEQ (1998a,b) indicates that ingestion and dermal contact exposures should be modified using an absorption efficiency. This accounts for the fact that the compound might not be completely absorbed by the body either through the gut or the skin. The oral absorption factor of 0.5 and the dermal absorption factor of 0.01 provided by MDEQ (1998b) were used in the calculations. Table L-8 provides the equations used to calculate exposure and risk for the site.

The exposure period evaluated in this risk assessment was developed assuming that the school year was 200 days. The MDEQ (1998a) guidance indicates that for four months of the year, the ground is frozen and direct contact exposure with soil would not be expected to occur. This would account for 80 days (5 days per week for 16 weeks) of the 200 day school year. Therefore, it was assumed that the individual might be exposed to soil for 120 days each year. This is a conservative assumption since it does not account for rainy days when contact with soil also might not occur.

Toxicity Assessment

Toxicity values for arsenic were obtained from the MDEQ (1998b). The U.S. EPA Integrated Risk Information System (IRIS), a database of toxicity data, was consulted to ensure that the values included in the MDEQ table were the most recent values available. Whenever possible, route-specific toxicity values are used. However, toxicity values for dermal exposure have not yet been developed by U.S. EPA; therefore, the oral toxicity values and the oral absorption efficiency were used to derive adjusted toxicity values (adjusted to the absorbed dose for use in assessing dermal exposure (U.S. EPA, 1995). A value of 0.95 was used in the adjustment, based on information provided by the Agency for Toxic Substances and Disease Registry (ATSDR; 1997).

Toxicity values are not available for lead. This is due to the fact that there is a strong correlation between exposure and resulting blood lead levels. Exposure to lead is discussed below.

Risk Characterization

The information presented in the Exposure and Toxicity Assessments were combined to characterize risk. A distinction is made between non-carcinogenic and carcinogenic endpoints, and two general criteria are used to describe risk: the hazard quotient (HQ) for non-carcinogenic effects and excess lifetime cancer risk (ELCR) for constituents evaluated as human carcinogens.

Hazard Quotient for Non-Cancer Risk

Exposure doses are averaged over the expected exposure period to evaluate non-carcinogenic effects. The HQ is the ratio of the estimated exposure dose and the RfD (for oral and dermal exposures) or the ratio of the exposure-weighted air concentration and the RfC (for inhalation exposures). An HQ greater than 1 indicates that the estimated exposure level for that constituent exceeds the RfD or RfC. This ratio does not provide the probability of an adverse effect. Although an HQ less than 1 indicates that health effects should not occur, an HQ that slightly exceeds 1 does not imply that health effects will occur, but that health effects are potentially possible. The sum of the HQs is the hazard index (HI). Both U.S. EPA

and MDEQ use an HI equal to 1 as the benchmark. HIs greater than 1 may indicate a potential risk to human health.

Excess Lifetime Cancer Risk

The ELCR is an estimate of the potential increased risk of cancer which results from lifetime exposure, at specified average daily dosages, to constituents detected in media at a site. Estimated doses or intakes for each constituent are averaged over the hypothesized lifetime of 70 years. It is assumed that a large dose received over a short period is equal to a smaller dose received over a longer period, as long as the total doses are equivalent. The ELCR is equal to the product of the exposure dose and the CSF (for oral/dermal exposure) or the product of the exposure-weighted air concentration and the UR_i (for inhalation exposure). The risk values provided in this report are an indication of the potential increased risk, above that applying to the general population, which may result from the exposure scenarios described in the Exposure Assessment. The risk estimate is considered to be an upper-bound estimate; therefore, it is likely that the true risk is far less than that predicted by the model.

Current U.S. EPA (1989) agency guidance states that a cumulative site cancer risk level of 10^{-4} is used as a remediation "trigger," meaning that risk levels below this level generally do not warrant remediation. Constituents are not considered as significant contributors to risk if their individual carcinogenic risk contribution is less than 10^{-6} (U.S. EPA, 1989). The acceptable risk level for carcinogenic risk is 10^{-6}; therefore, 10^{-6} is used as the agency benchmark in considering the potentially acceptable risk levels for cancer effects (U.S. EPA, 1989). The MDEQ uses 10^{-5} as their benchmark for excess cancer risks.

Calculated Risk Estimates for Arsenic

Risk estimates for exposure to arsenic in soil are presented in Table P-2. Table P-2 provides the results of the calculations presented in Table P-1. As seen in the table, the ELCR for exposure to arsenic is 5×10^{-7}. This ELCR is well below the MDEQ benchmark of 1×10^{-5}. The HI was 0.01, well below the MDEQ benchmark. Therefore, there is no risk from exposure to arsenic under these exposure assumptions.

Exposure to Lead

Exposure to lead is evaluated by estimating the blood lead levels that would result in the potentially exposed individual from exposure to lead. The U.S. EPA has developed several models for the evaluation of exposure to lead. One is the Integrated Exposure Uptake Biokinetic (IEUBK) model (U.S. EPA, 1994). The IEUBK model is used to assess blood lead levels in children up to age 7 chronically exposed to lead. The IEUBK model integrates exposure to lead in air, water, soil, dust, and diet with pharmacokinetic modeling to predict blood lead levels in children. Children exposed to lead in soil at the RDA are ages 5 years old to 10 years old. The youngest of these children are thought to be the most susceptible to lead exposure. Additionally, the IEUBK model can be used to evaluate exposure for children ages 5 to 6 years old and ages 6 to 7 years old.

The IEUBK model was run using the maximum detected lead concentration of 610 mg/kg. The model using its default parameters assumes that the soil lead concentration also would be detected in dust in the home. The area of impacted lead is not large and it is likely that any dust adhering to the child's clothing or shoes would be deposited prior to arriving home. Therefore, the model was run assuming that the lead level in dust was 0 mg/kg. Using this approach, the resulting blood lead concentrations for children ages 5 to 6 years old and ages 6 to 7 years old were 3.5 micrograms per deciliter (µg/dL) and 3.2 µg/dL, respectively. Compared with the U.S. EPA benchmark of 10 µg/dL, there is no risk from exposure to these lead levels. If dust exposure at this maximum level were included in the calculations, then the resulting blood lead concentrations for children ages 5 to 6 years old and ages 6 to 7 years old would increase to 6.0 µg/dL and 5.4 µg/dL, respectively, again below the U.S. EPA benchmark.

Because we care
100% recycled paper produced by wind power energy.

Summary and Conclusions

Surface soil data were collected at the RDA. The data were compared with the MDEQ screening values for residential exposures. Three samples contained constituent concentrations exceeding these values. Arsenic and lead were identified as constituents of potential concern in that they exceeded the MDEQ screening values in one or more samples.

Exposure was evaluated for a child walking over the RDA to attend the Woodland Elementary School. The school has grades Kindergarten through Fifth Grade. Therefore, it was assumed that the individual might be exposed for a maximum of a 6 year period. Exposure to arsenic and lead does not pose a risk to this individual, based on the exposure assumptions considered in this risk assessment.

where:

$$EPC_{air} = \frac{EPC_S}{PEF} \quad \text{(for particulates)}$$

$$PEF = Q/C \times \frac{3{,}600\ sec/hr}{RPF \times (1-V) \times (Um/Ut)^3 \times F_X}$$

CANCER RISK:

$$ELCR = ELCR_o + ELCR_d + ELCR_i$$

NON-CANCER RISK:

$$HI = HQ_o + HQ_d + HQ_i\ 1$$

where:

ABS_d	Dermal absorption efficiency (0.01 for arsenic; MDEQ 1998b).
ABS_o	Oral absorption efficiency (0.5 for arsenic; MDEQ 1998b).
AP_C	Averaging period for cancer effects (25,550 days [70 years]).
AP_{NC}	Averaging period for non-cancer effects (2,190 days [6 years]).
BW	Body weight (37.5 kg) (USEPA, 1997).
CSF	Cancer slope factor for oral (CSF_o) or dermal (CSF_a) exposure (kg-day/mg; inverse of mg/kg/day) (1.5 kg-day/mg for oral exposure and 1.6 kg-day/mg for dermal exposure) .
EF	Exposure frequency (120 days/year).
ELCR	Excess lifetime cancer risk (unitless).
EPCair	Exposure point concentration in air (1.36×10^{11} mg/m^3).
EPCs	Exposure point concentration in soil (16 mg/kg which is the maximum arsenic concentration detected).
EP	Exposure period (6 years).
F_X	Function of Ut/Um (unitless); $F_X = 0.18 \times [\ 8x^3 + 12x\ ] \times \exp[-(x^2)]$, where $x = 0.886 \times (Ut/Um)$.
HI	Hazard index (unitless); sum of the HQs.
HQ	Hazard quotient (unitless).
IR_S	Ingestion rate of soil (50 mg/day).

Table Q-1. Risk Equations for Trespasser Exposure to Soil, Riverside Disposal Area, Ford/Kingsford Site, Kingsford, Michigan.

IRC Inhalation rate correction factor (1; unitless).
PEF Particulate emission factor (m^3/kg).
Q/C Emission flux per unit concentration [90.8 (g/m^2/sec)/(kg/m^3), USEPA (1996) value for a 0.5-acre site in Minneapolis, MN].
RfC Reference concentration for inhalation exposure (mg/m^3) (Not available for arsenic).
RfD Reference dose for oral (RfD_o) or dermal (RfD_a) exposure (mg/kg/day) (3.0×10^{-4} mg/kg/day for oral exposure and 2.9×10^{-4} for dermal exposure).
RPF Respirable particle fraction (0.036 g/m^2/hr) (USEPA 1996).
SAR Soil adherence rate (0.2 mg/cm^2/day) (USEPA 1997).
SC Source contribution (1; unitless).
SSA Exposed skin surface area (2,435 cm^2).
UR_i Unit cancer risk for inhalation exposure (m^3/mg) (4.3×10^{-3} m^3/mg for arsenic).
U_m Wind speed (3.7 m/sec) (for Marquette, MI; NOAA 1975).
U_t Equivalent threshold value of windspeed at 7 meters (12.94 m/sec) (Cowherd 1984).
V Fraction of vegetative cover (unitless) (0.9).
x Intermediate value in calculation of PEF; x = 0.886 × (Ut/Um).

SAMPLE CALCULATION: Arsenic

$$x = 0.886 \times (12.94 \text{ m/sec})/(3.7 \text{ m/sec}) = 3.099$$

$$F_X = 0.18 \times \left[\left(8 \times 3.099^3\right) + \left(12 \times 3.099\right)\right] \times \exp\left[-\left(3.099^2\right)\right] = 0.0033$$

$$PEF = 90.8 \frac{\text{g/m}^2\text{/sec}}{\text{kg/m}^3} \times \frac{3{,}600 \text{ sec/hr}}{(0.036 \text{ g/m}^2\text{/hr}) \times (1 - 0.9) \times \left(\frac{3.7 \text{ m/sec}}{12.94 \text{ m/sec}}\right)^3 \times 0.0033} = 1.18 \times 10^{12} \text{ m}^3/\text{kg}$$

CANCER RISK:

$$ELCR_o = \frac{(16 \text{ mg/kg}) \times (1) \times (50 \text{ mg/day}) \times (0.5) \times (120 \text{ days/yr}) \times (6 \text{ yr})}{(10^6 \text{ mg/kg}) \times (37.5 \text{ kg}) \times (25{,}550 \text{ days}) \times [1/(1.5 \text{ kg} \cdot \text{day/mg})]}$$

$$= 4.5 \times 10^{-7}$$

$$ELCR_d = \frac{(16 \text{ mg/kg}) \times (1) \times (2{,}435 \text{ cm}^2) \times (0.2 \text{ mg/cm}^2\text{/day}) \times 0.01 \times (120 \text{ days/yr}) \times (6 \text{ yr})}{(10^6 \text{ mg/kg}) \times (37.5 \text{ kg}) \times (25{,}550 \text{ days}) \times [1/(1.6 \text{ kg} \cdot \text{day/mg})]}$$

$$= 9.3 \times 10^{-8}$$

Table Q-1. Risk Equations for Trespasser Exposure to Soil, Riverside Disposal Area, Ford/Kingsford Site, Kingsford, Michigan.

$$ELCR_i = \frac{(16\ mg/kg) \times (1) \times [1/(1.18\times10^{12}\ m^3/kg)] \times (120\ days/yr) \times (6\ yr)}{(25{,}550\ days) \times \left(\frac{0.001 mg/\mu g}{4.3\times10^{-3}\ m^3/\mu g}\right)}$$

$$= 1.6\times10^{-12}$$

$$ELCR = (4.5\times10^{-7}) + (9.3\times10^{-8}) + (1.6\times10^{-12}) = 5\times10^{-7}$$

NON-CANCER RISK:

$$HQ_o = \frac{(16\ mg/kg) \times (1) \times (50\ mg/day) \times (0.5) \times (120\ days/yr) \times (6\ yr)}{(10^6\ mg/kg) \times (37.5\ kg) \times (2{,}190\ days) \times (0.0003\ mg/kg/day)}$$

$$= 0.012$$

$$HQ_d = \frac{(16\ mg/kg) \times (1) \times (2{,}435\ cm^2) \times (0.2\ mg/cm^2/day) \times 0.01 \times (120\ days/yr) \times (6\ yr)}{(10^6\ mg/kg) \times (37.5\ kg) \times (2{,}190\ days) \times (0.00029\ mg/kg/day)}$$

$$= 0.0024$$

$$HQ_i = \frac{(16\ mg/kg) \times (1) \times [1/(1.18\times10^{12}\ m^3/kg)] \times (120\ days/yr) \times (6\ yr)}{(2{,}190\ days) \times (NA)}$$

= Not applicable; an RfC is not available for arsenic

$$HI = (0.012) + (0.0024) + (NA) = 0.01$$
